EIC Accelerator Performance

Requirements for an Electron-Ion Collider are defined in the White Paper:

“In order to address the crucial scientific questions discussed in the previous sections, the EIC must provide:

- *A **Highly polarized** electron ($\sim 70\%$) and **proton** ($\sim 70\%$) beams;*
- *Ion beams from deuterons to heavy nuclei such as gold, lead, or uranium;*
- *Variable $e+p$ center-of-mass energies from 29–140 GeV;*
- ***High collision electron-nucleon luminosity** $10^{33}–10^{34} \text{ cm}^{-2} \text{ s}^{-1}$;*
- *The possibility to have more than one interaction region.”*

In accordance with the requirements of the "White Paper," it is necessary to improve both the polarization and the intensity of the polarized proton beam.

“White Paper on the Electron-Ion Collider in Preparation for the NSAC Long Range Plan EIC”, p.5 User Group, January 2, 2023

Introduction

For 25 years, the polarized proton source based on OPPIS (Optically Pumped Polarized Ion Source) reliably delivered the high-intensity polarized proton beam for the RHIC spin physics program.

The OPPIS polarized source ECR-type (Electron Cyclotron Resonance) for RHIC was developed in collaboration BNL – KEK – TRIUMF – INR at 1998-2002.

The source has been upgraded several times and continuously improves polarization, intensity and emittance.

- * Prior to Run-12, the ECR-type source was used to generate the primary proton beam.
- * In 2012, the ECR-source was replaced by a high-brightness OPPIS source FABS-type (Fast Atomic Beam Source).
- * Unlike the ECR-type source, the FABS-type source operates in pulsed mode and is located outside the SCS magnet.
- * This new source has enabled improvements in beam parameters such as current density, emittance, and stability.

Polarization transfer technique (OPPIS)

Circular polarized laser beam (tunable wavelength $\sim 795\text{nm}$)

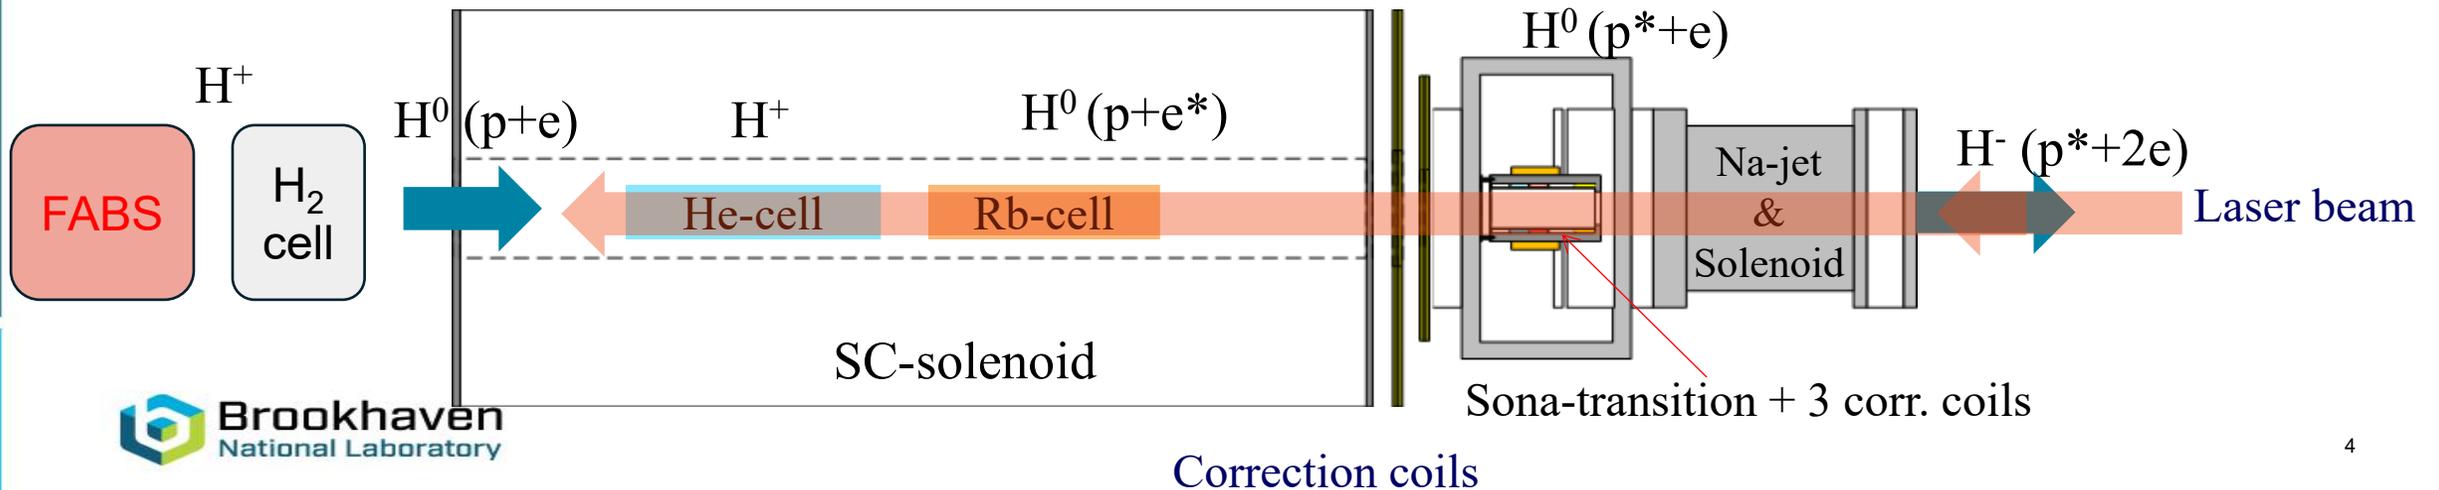

Ionization of hydrogen atom (ECR or FABS).

Polarization of the Rb-atom (Rb-cell)

Production of electron spins polarized hydrogen atoms by capturing an electron from Rb

Polarization transfer from the electron to proton by “Sona-transition” technique

The ionization of hydrogen atoms by capturing a second electron in Na-jet for acceleration (Na-cell)

Polarization transfer technique milestones

- **1944- E. Zavoisky – Electron Paramagnetic Resonance.**
- **1966- Nobel prize A. Kastler, Optical Pumping Polarization Technique.**
- 1969 – M. Kaminskiy – experiment. Deutrons + magnetized nickel crystal.
- 1972 – B. Ad'yasevich – experiment. Protons on polarized by 6-pole hydrogen.
- 1978 – G.Witteveen –experiment. Protons +polarized by 6-pole magnet Na-vapor.
- 1978 – E.Shamovskiy, Y.Shatunov – proposal. Protons + Cs (6-pole). For the first time, the necessity of high field in neutralization region was pointed out.
- 1979 – L.W.Anderson – proposal. Optical pumping of Na-vapor by commercially available lasers. High field in the Na-cell to prevent depolarization.
- 1981- A.Zelenski -proposal to avoid emittance grows, by using atomic H-injector and He- ionizer cell placed in the same strong magnetic field as optically- pumped Na-vapor cell. Optical pumping of the high –thickness Na-cell by pulsed dye laser.
- 1981 – Y.Mori, W.Cornelius - proposal to use ECR-proton source in the high field to avoid beam emittance growth.
- 1983 – Y.Mori – experiment. The first operational OPPIS with the ECR primary proton source (40 uA, P=50%).
- 1984-1885 – A.Zelenski –exp. Pulsed OPPIS – H⁻ current 0.1 mA. H⁺ - 1.0 mA. H⁻ current 0.4mA. H⁺ - 4.0 mA, P =65%.
- 1986 – L.W.Anderson, D.Swenson- spin-exchange polarization (proposal).
- 1986 –1990 - A.Zelenski – exp. Spin-exchange polarization in Na and Rb vapors.
- 1992-1999 - A dc OPPIS development for “Parity” experiment at TRIUMF. Spin- correlated current modulations 10 –5 level, energy modulations <5 meV. The “Parity” experiment completed.
- 1995- A.Zelenski –exp. DC OPPIS – H⁻ current 1.0 mA. P=75%.
- 1996 - Y.Mori – exp. Polarized D⁻ production in the OPPIS with dual optical pumping. P_z –70%, current 300 uA.
- 1999 – A.Zelenski-Polarized H⁻ current of a 10.0 mA achieved in the pulsed OPPIS. P = 40% (limited by available solenoidal field strength)
- 1999 - OPPIS development for RHIC was completed at TRIUMF. Final tests with TRIUMF superconducting solenoid. H⁻ current 1.6 mA, P = 85%.
- 2000 - The first OPPIS operation at RHIC.
- 2002 –2003 – RHIC OPPIS operation. 0.5 mA at 200 MeV. P = 80%.

oscillator tube

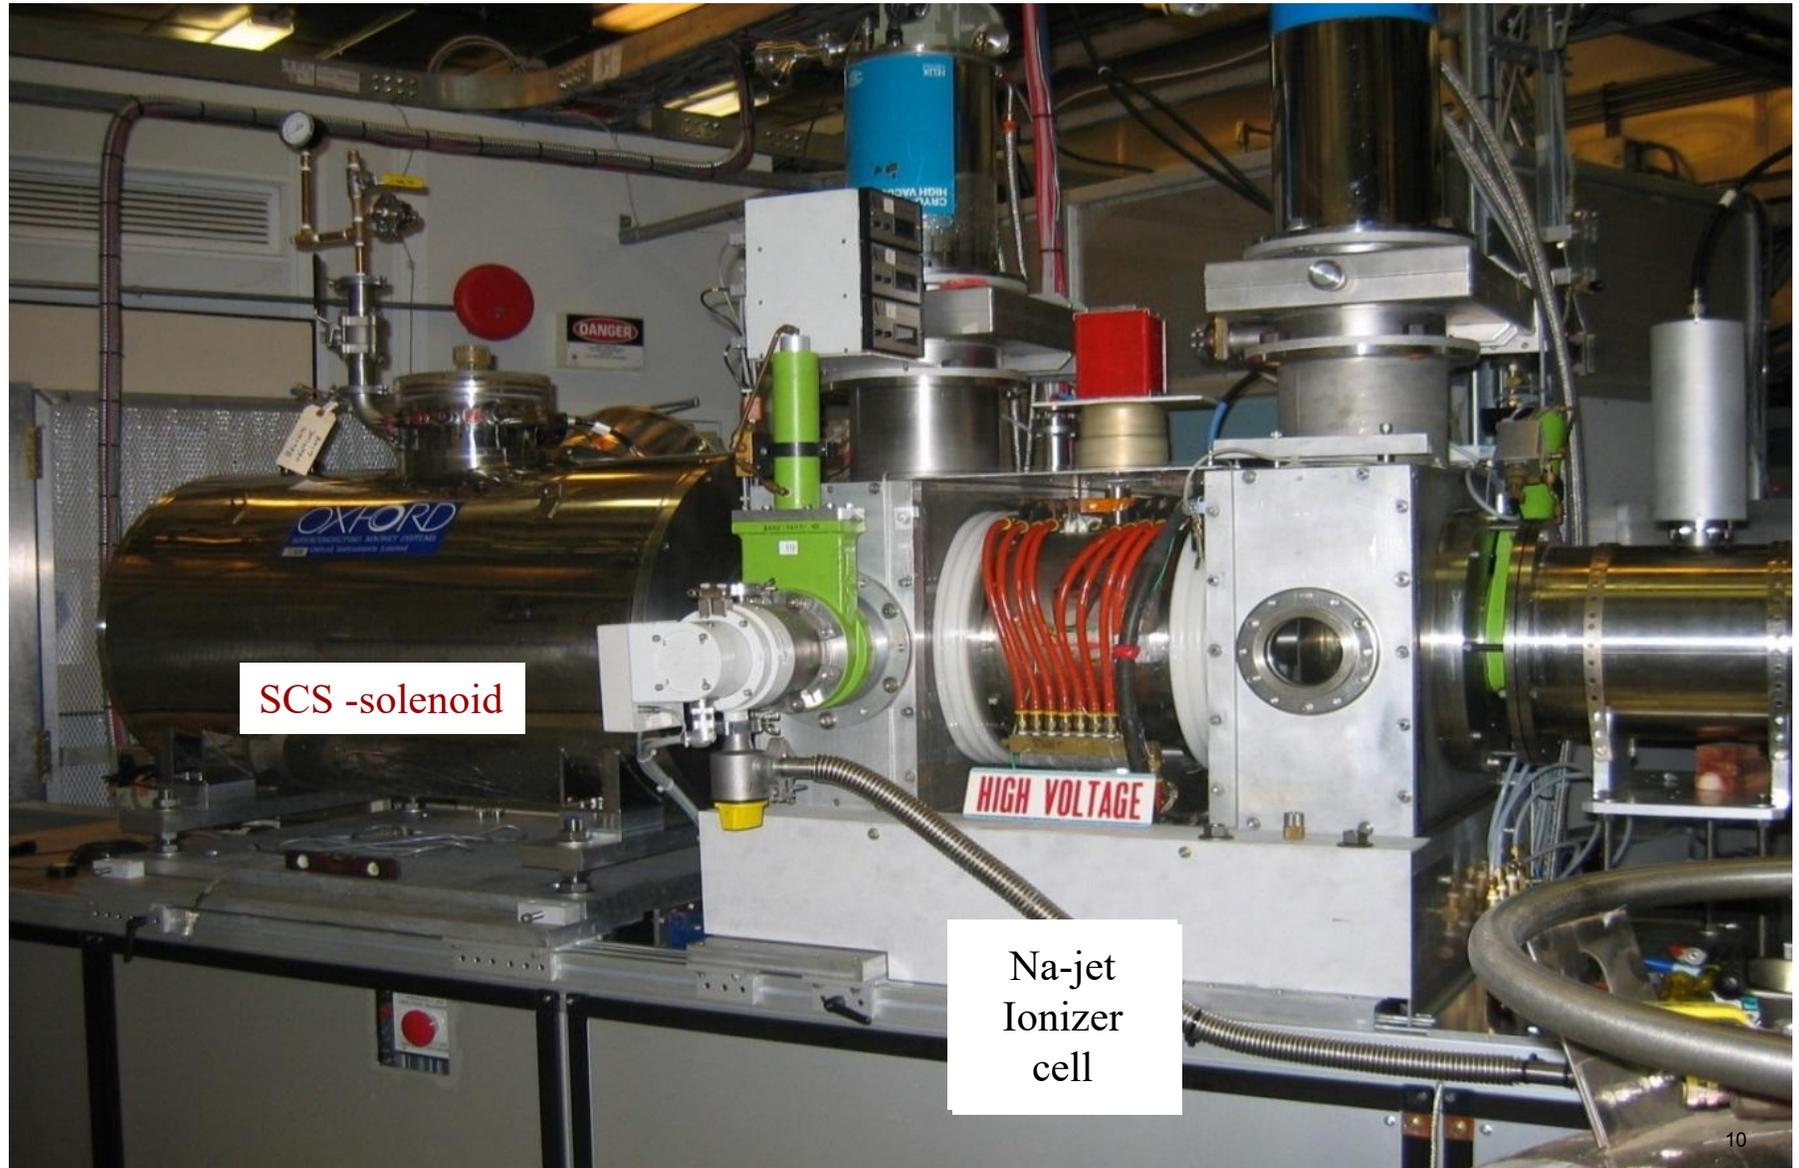

OPPIS produces
reliably 0.5-1.0mA
polarized H⁻ ion current.

Polarization at 200MeV:
P = 80%.

Beam intensity
(ion/pulse):

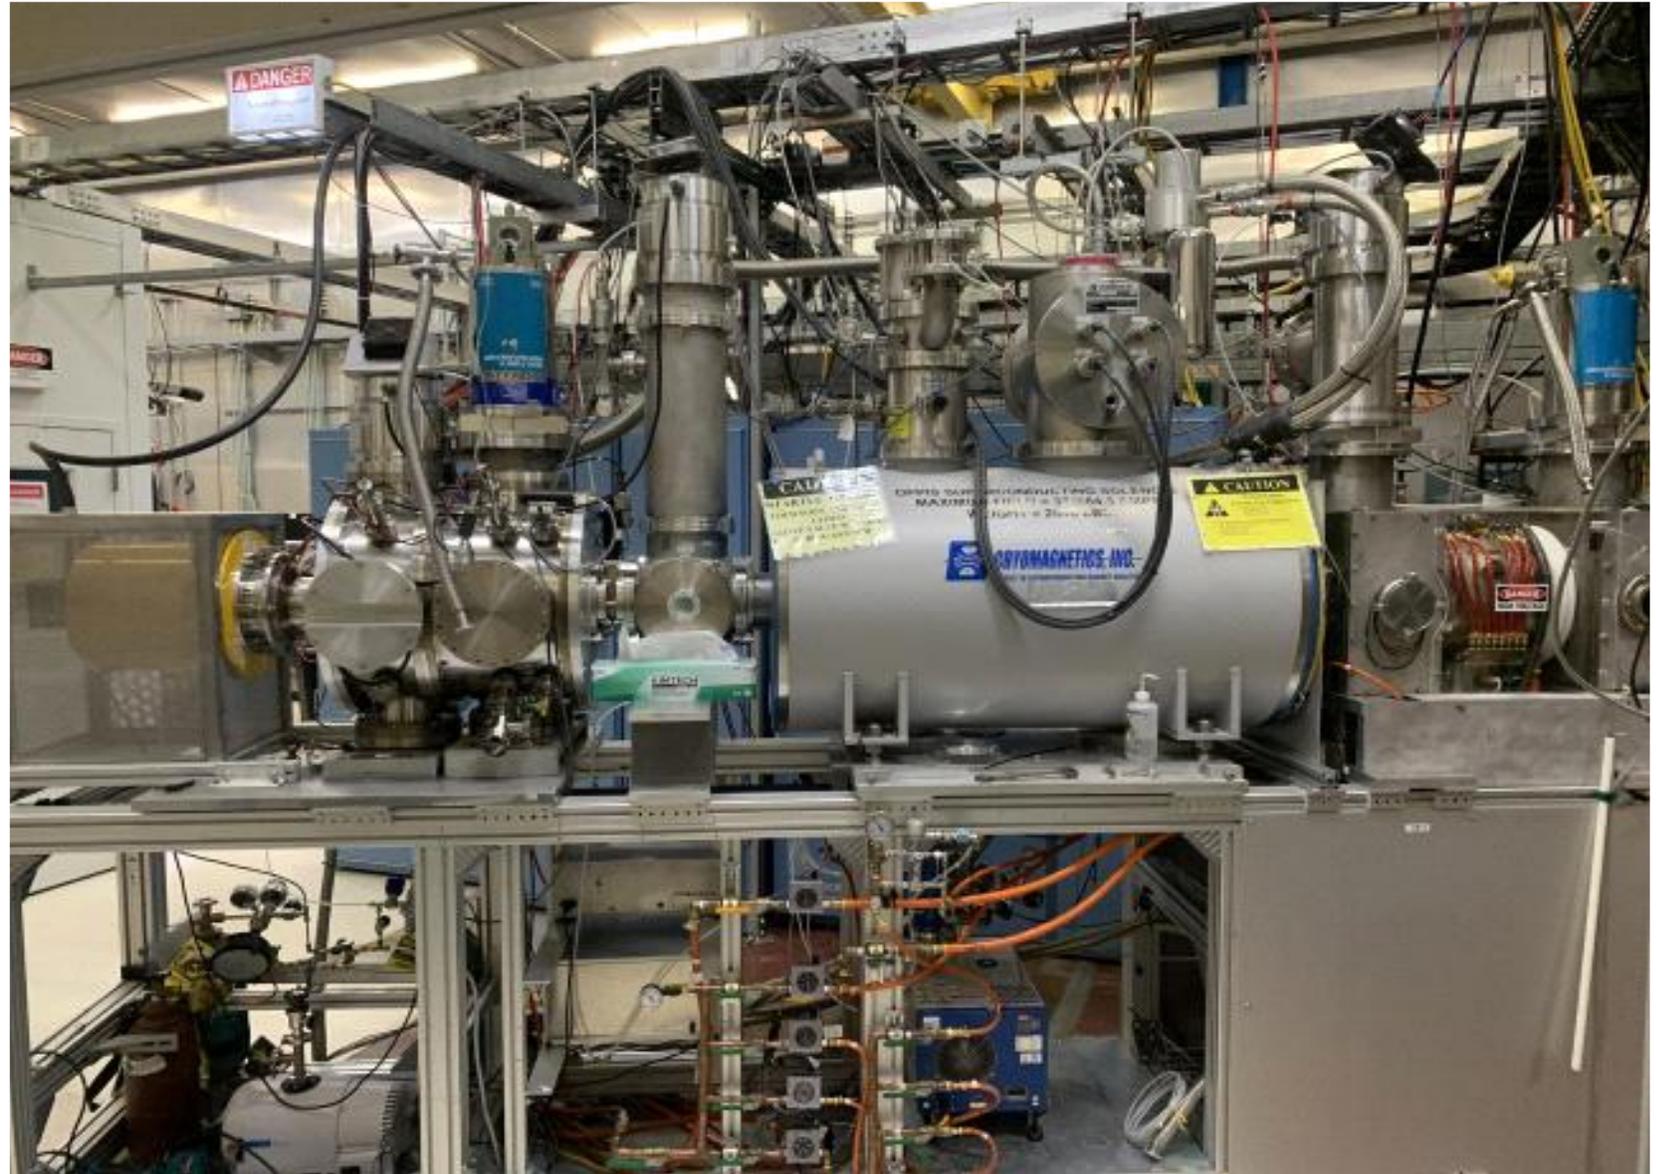

Source - 10^{12} H/pulse

Linac - $5 \cdot 10^{11}$ H/pulse

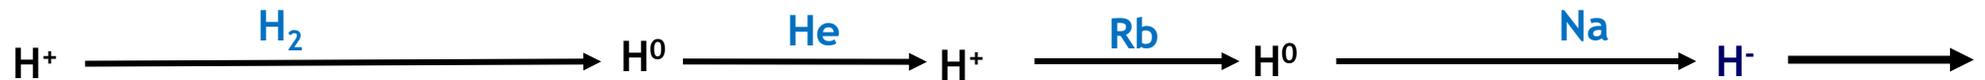

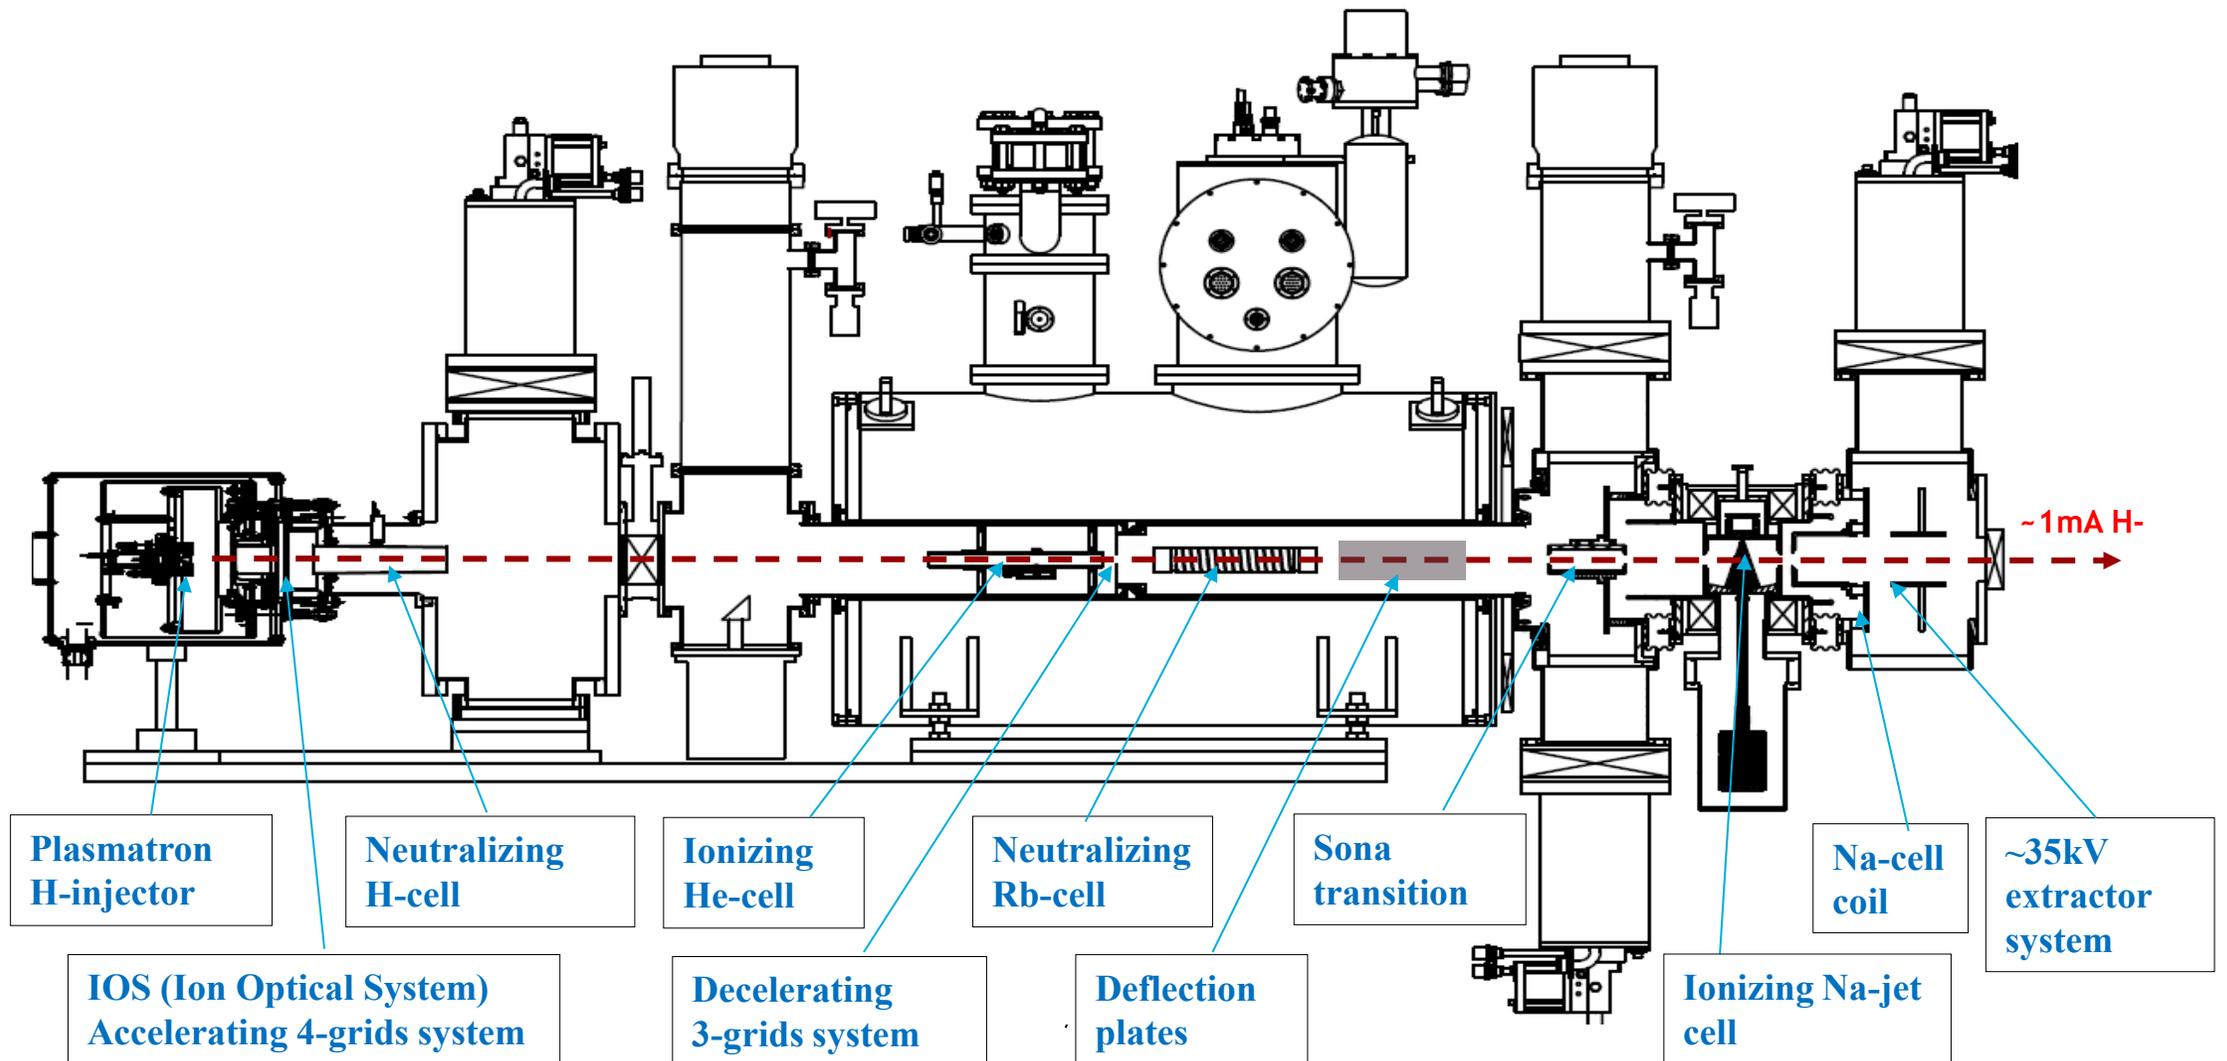

2013 OPPIS upgrade with FABS source

A ten-fold intensity increase was demonstrated in a pulsed operation by using a very high-brightness Fast Atomic Beam Source instead of the ECR proton source .

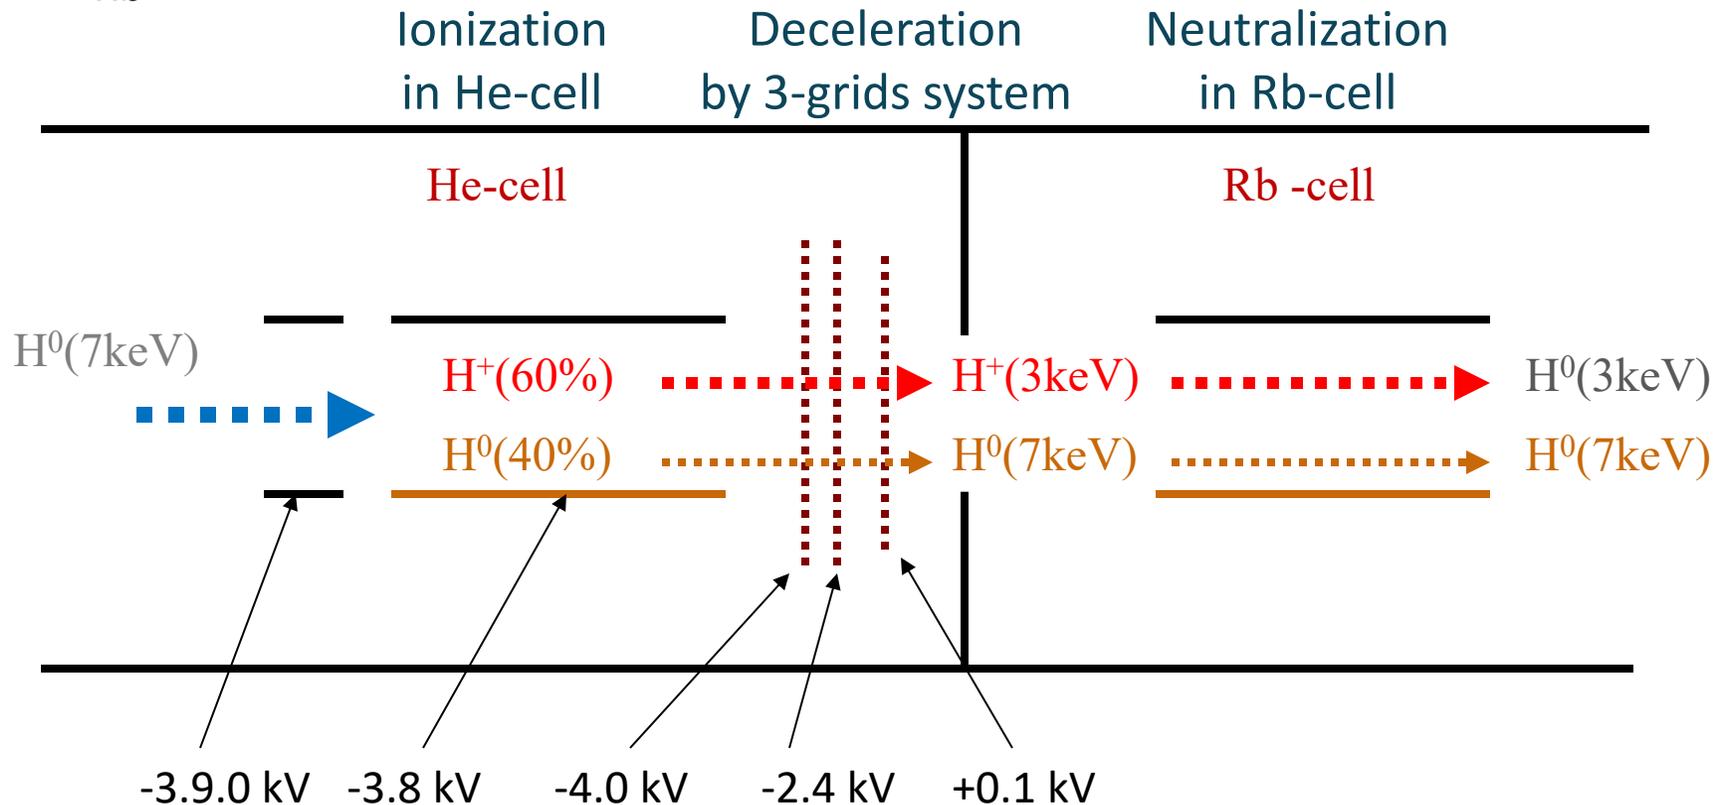

2013 OPPIS upgrade with FABS source

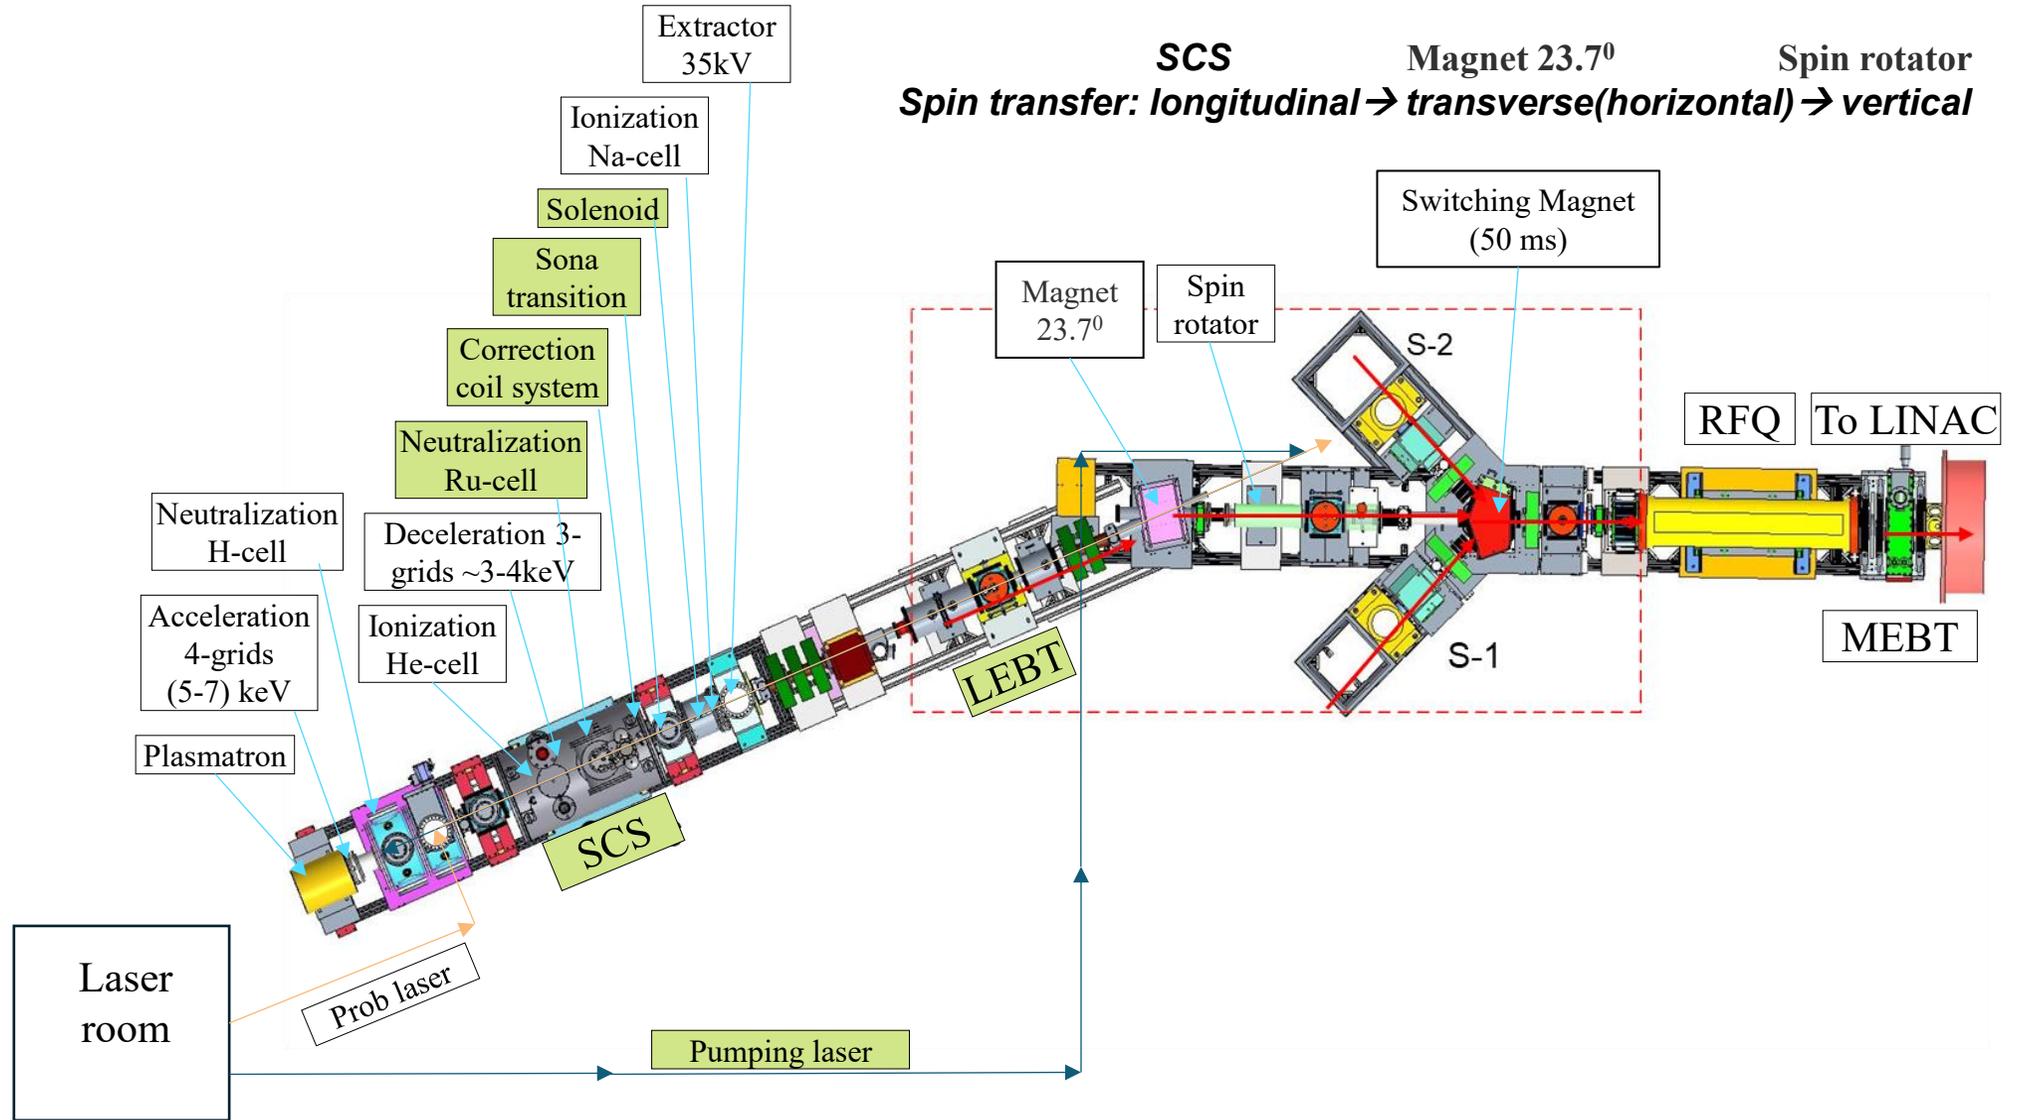

Energy separation a residual un-polarized H⁰ component

Only a portion of the beam is ionized in the He-cell (~60%) and can be further polarized.

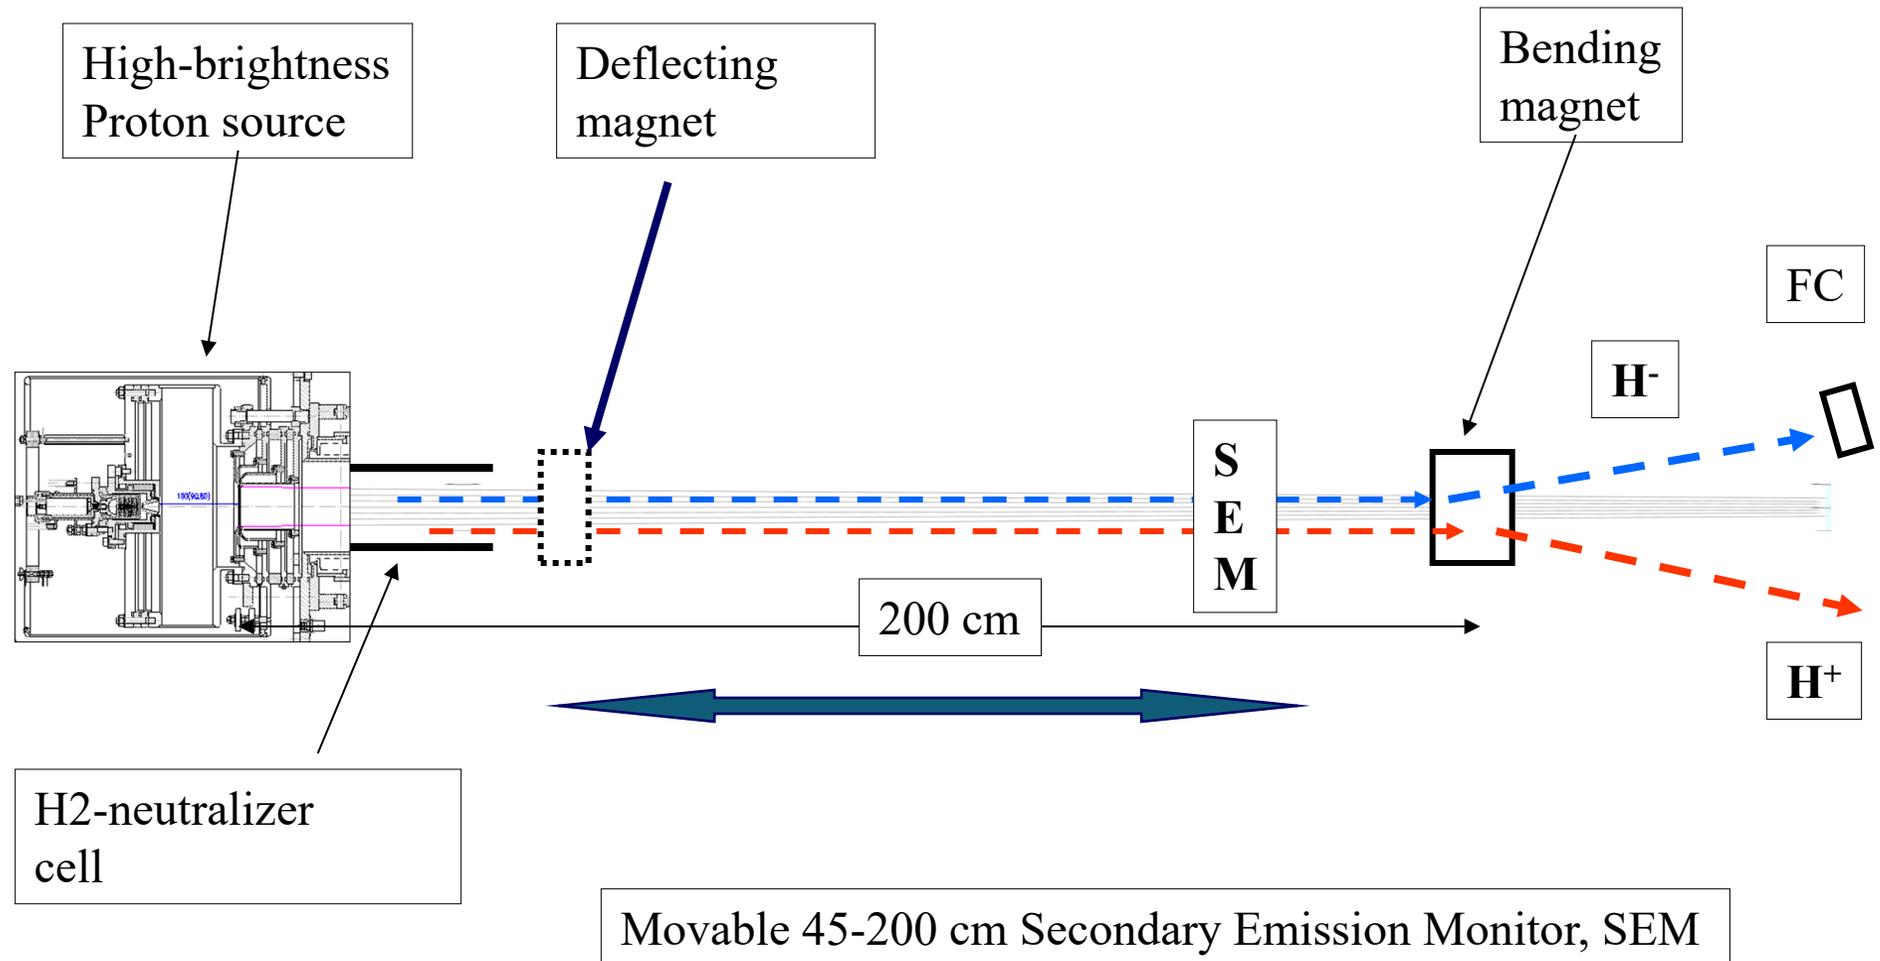

The polarized part of the beam separates from the un-polarized by the bending magnet, LEBT (quadrupoles and steering magnets) and collimators. Energy separation ratio H⁺(4keV)/H⁺(7keV) is better by 25-30 times.

Optically Polarized proton source (OPPIS)

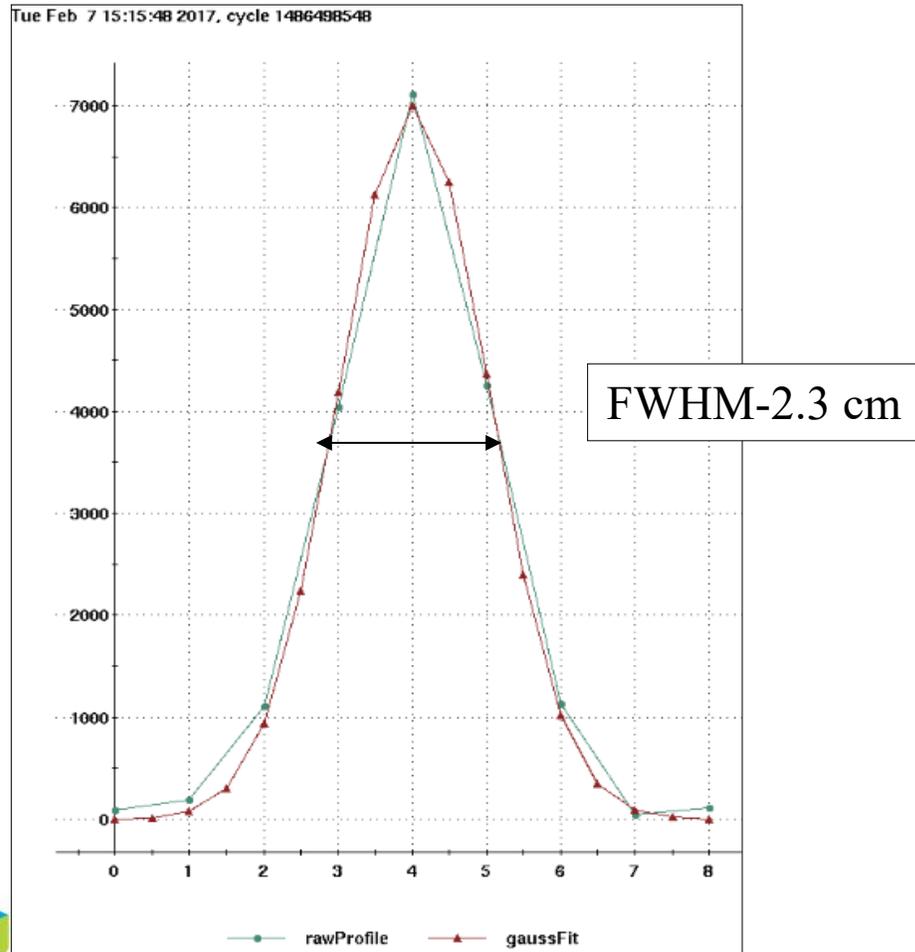

Atomic beam profile measurements on test bench

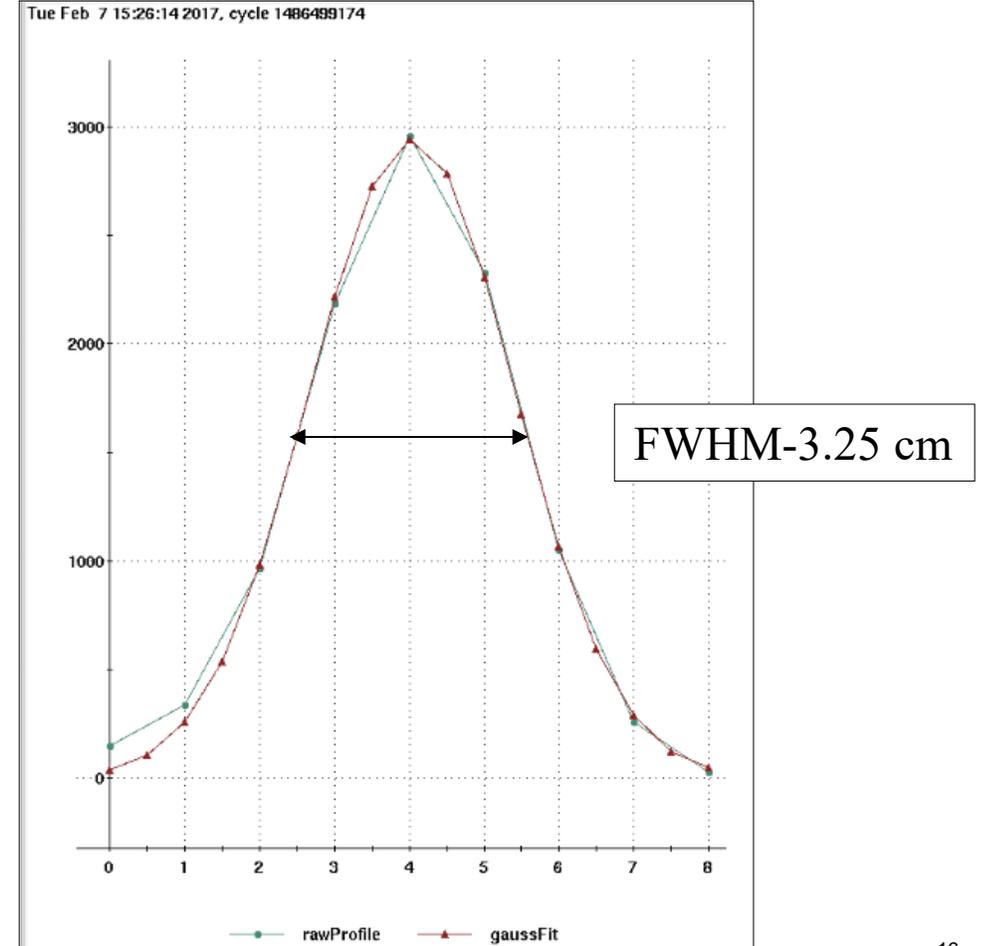

Atomic beam intensity profile vs. distance from the source

The measurement was performed using a movable (range: 45–200 cm) 9-channel secondary emission monitor (SEM).

Re-1.40 cm at the distance:
L=100 cm-from the source

Re-1.98 cm at the distance:
L=200 cm-from the source

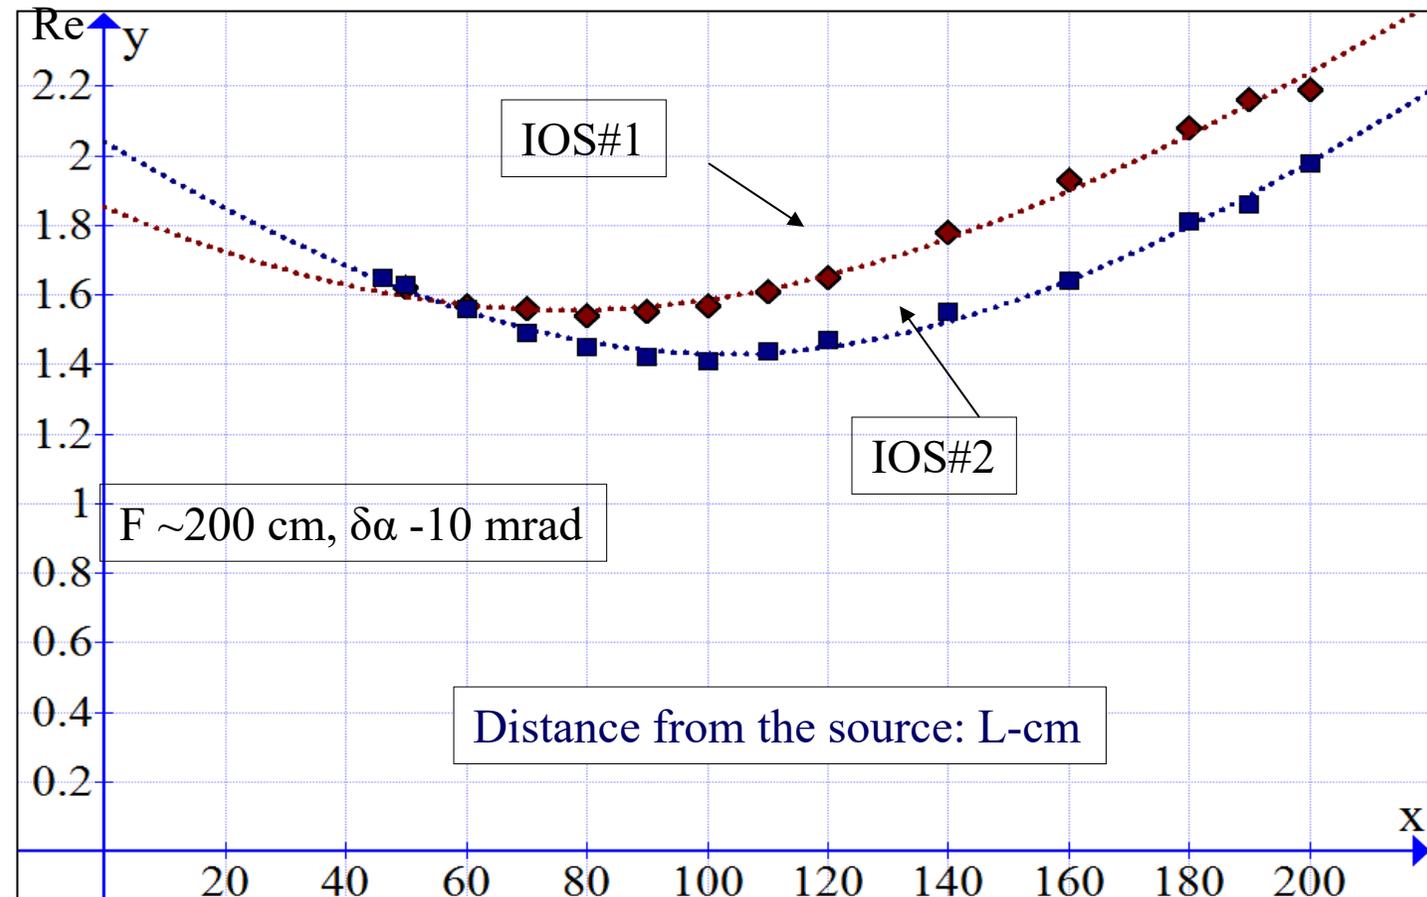

Atomic beam intensity profile vs. distance from the source

The measurement was performed using a movable (range: 45–200 cm) 9-channel secondary emission monitor (SEM).

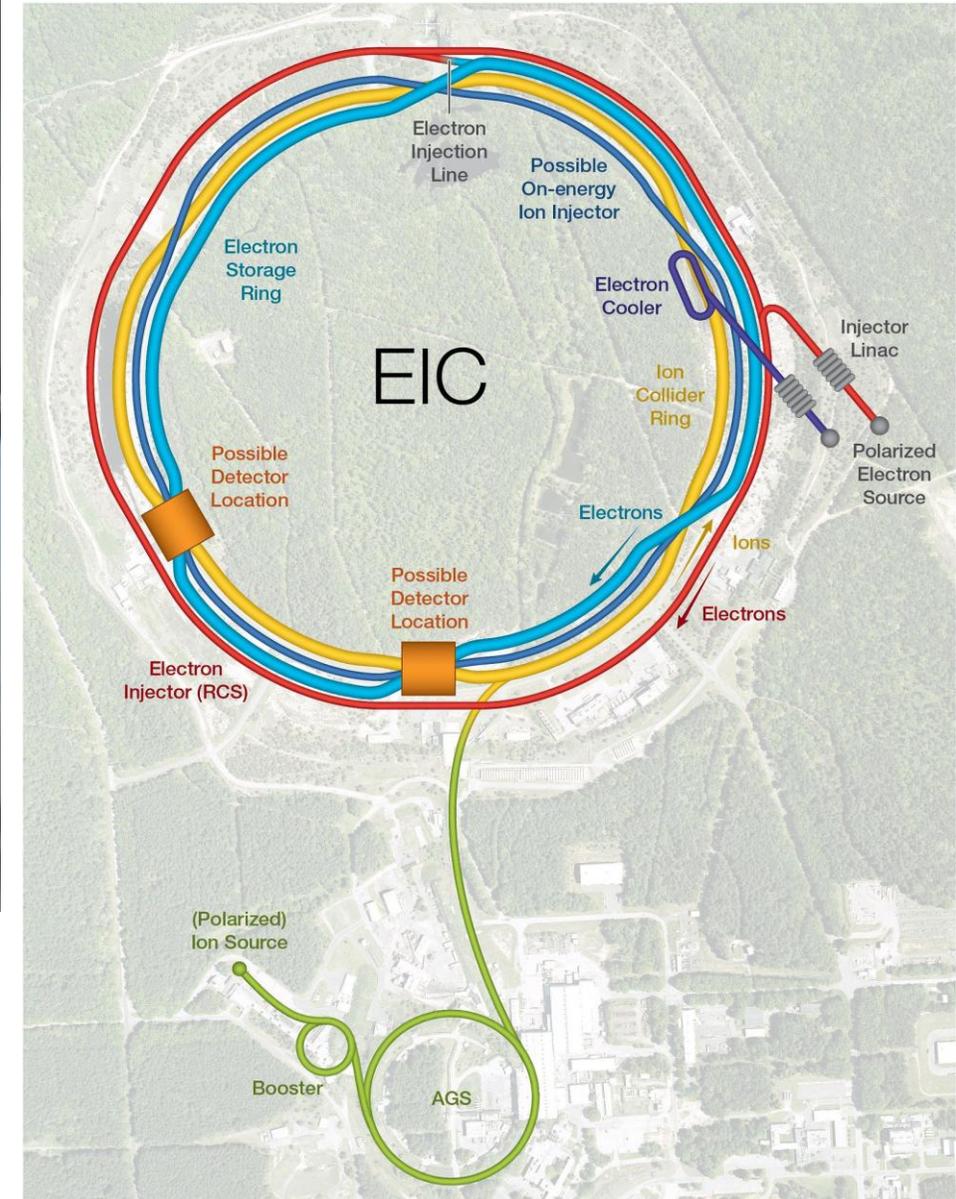

Total equivalent H beam intensity 2.5A

Beam profile FWHM = $1.67 Re$

A Smashing Success: Relativistic Heavy Ion Collider Wraps up Final Collisions

February 6, 2026

Media & Communications Office Newsroom

Performance of source at RHIC Run-26 (Dec 9, 2025 - Feb 6, 2026)

Average current : $\sim 420 \mu\text{A}$
 pulse width : $\sim 300 \mu\text{sec}$
 average polarization : $\sim 82\%$
 at 200 MeV after the Linac.

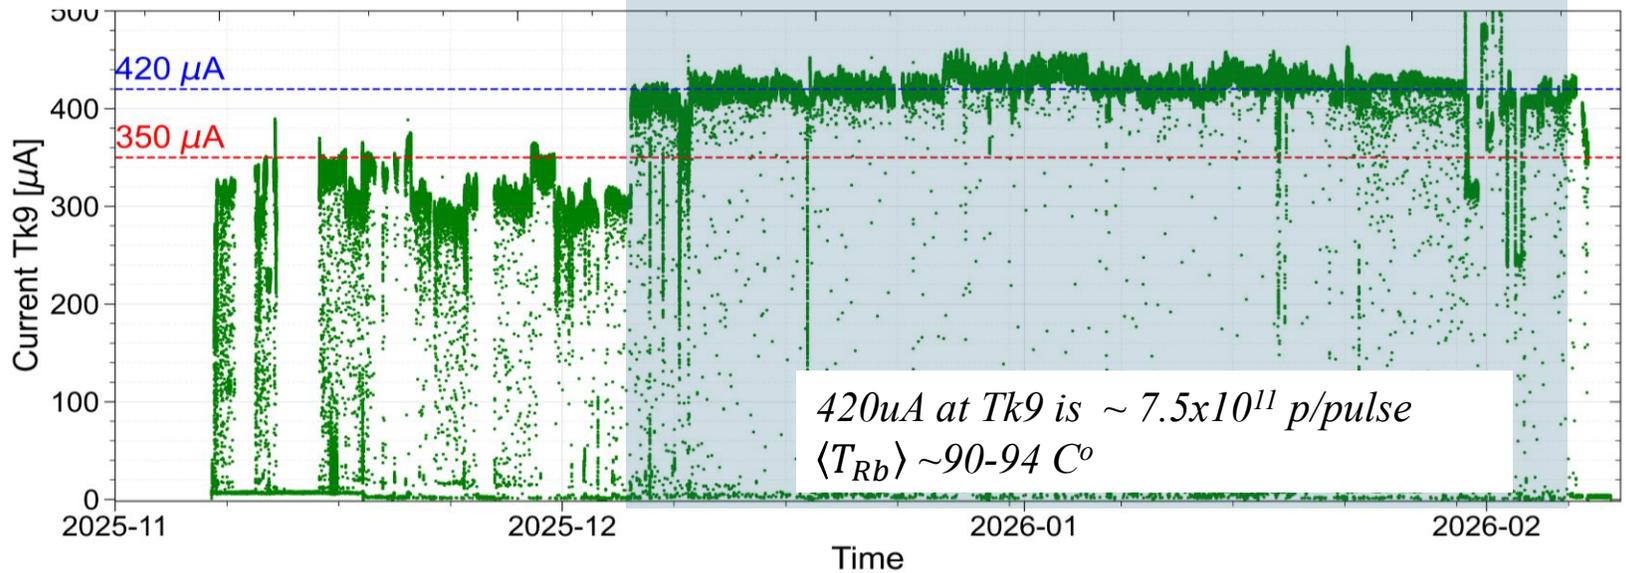

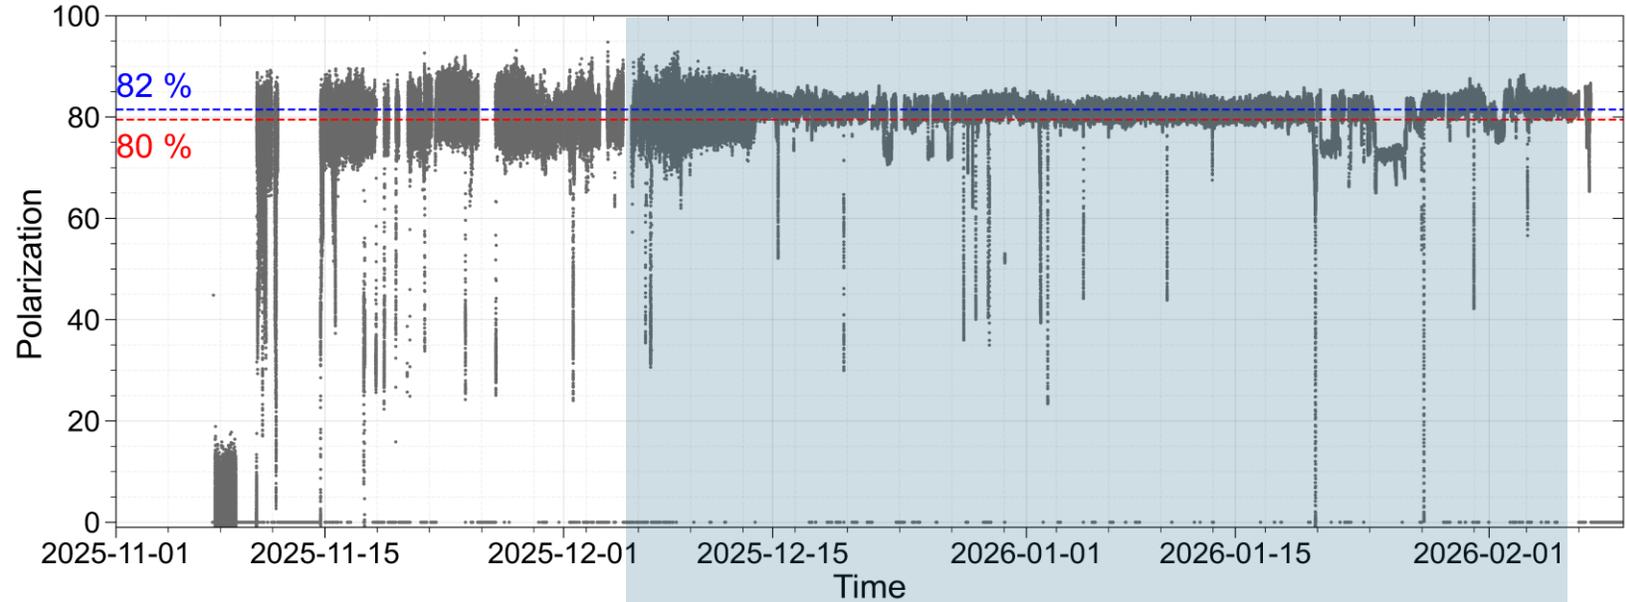

At present AGS and RHIC beam intensity acceptances are limited by about $1 \cdot 10^{11}$ p/bunch. The intensity excess was used to reduce transversal and longitudinal beam emittances by a strong dynamical collimation in the Booster.

High beam polarization is crucial for reducing statistical uncertainties in polarized experiments. The statistic error of the double spin asymmetry is:
 $\sigma_{\text{stat}} \sim 1/p^2$.

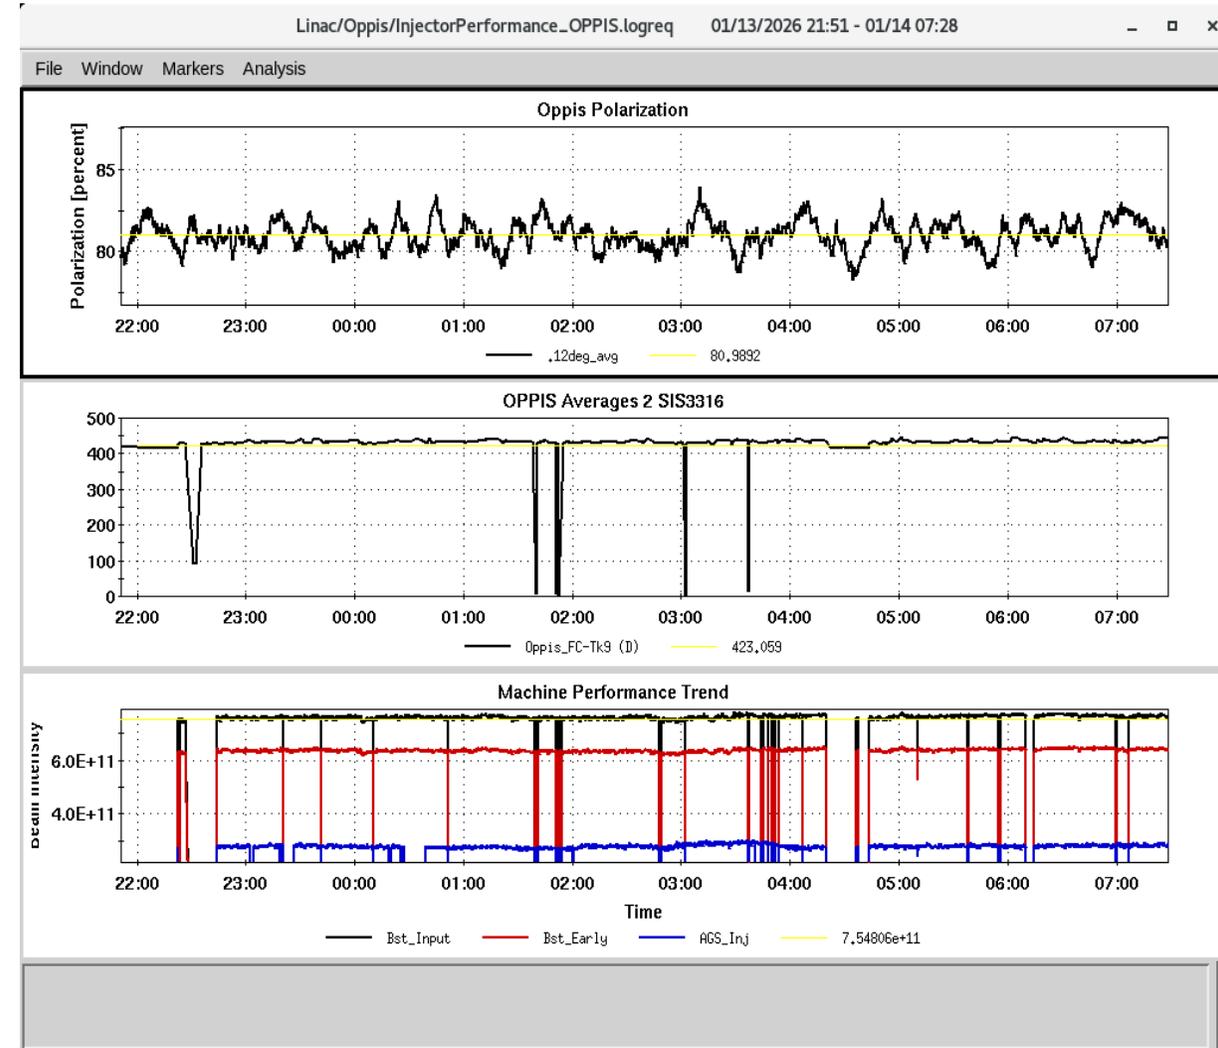

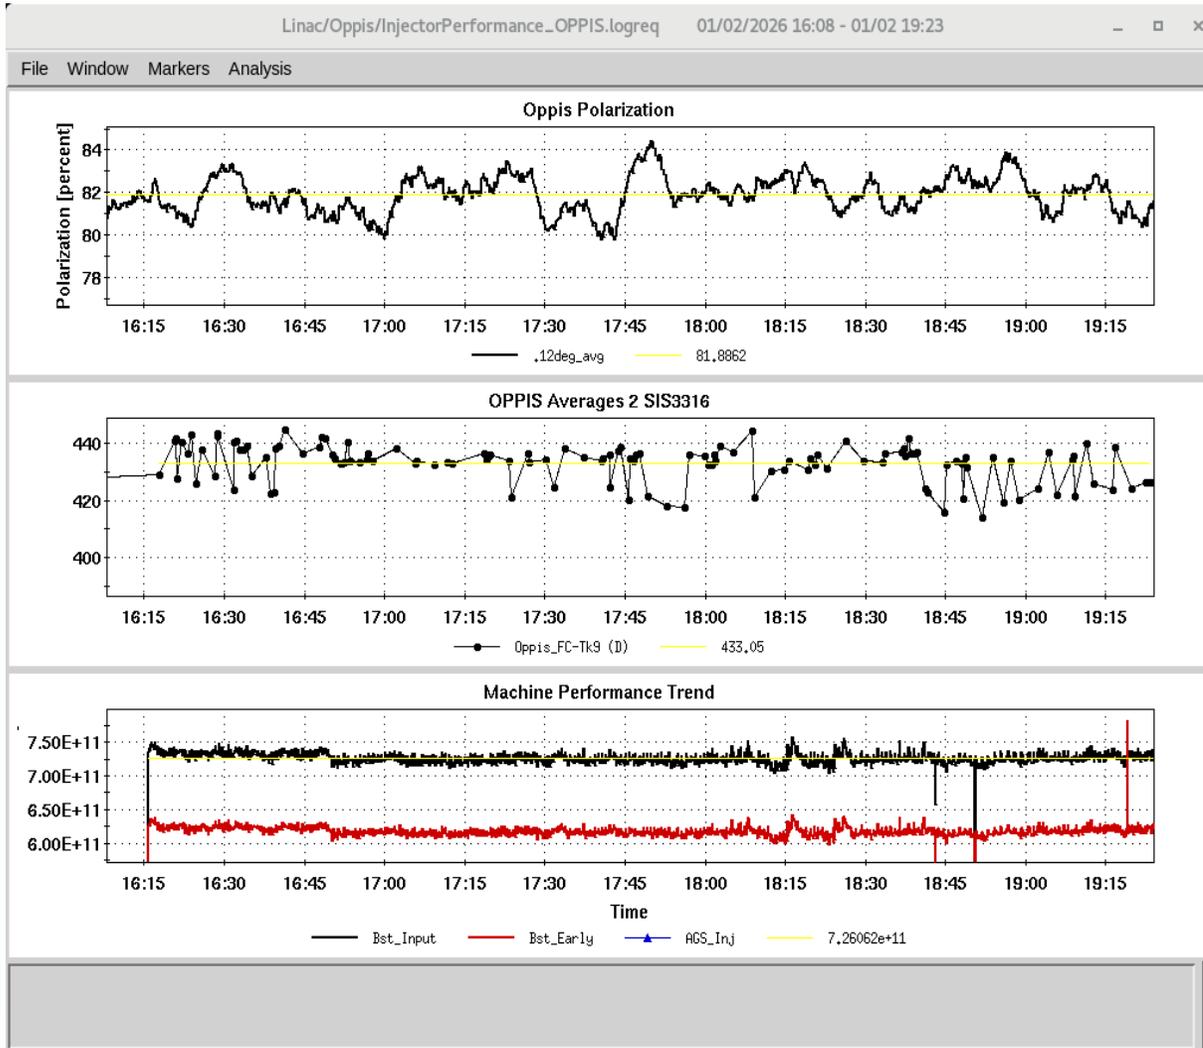

Increasing the source polarization from 80% to 85% is equivalent to more than 25% more data-taking time.

Beam intensity and polarization must be equal at spin-reversal and from pulse to pulse.

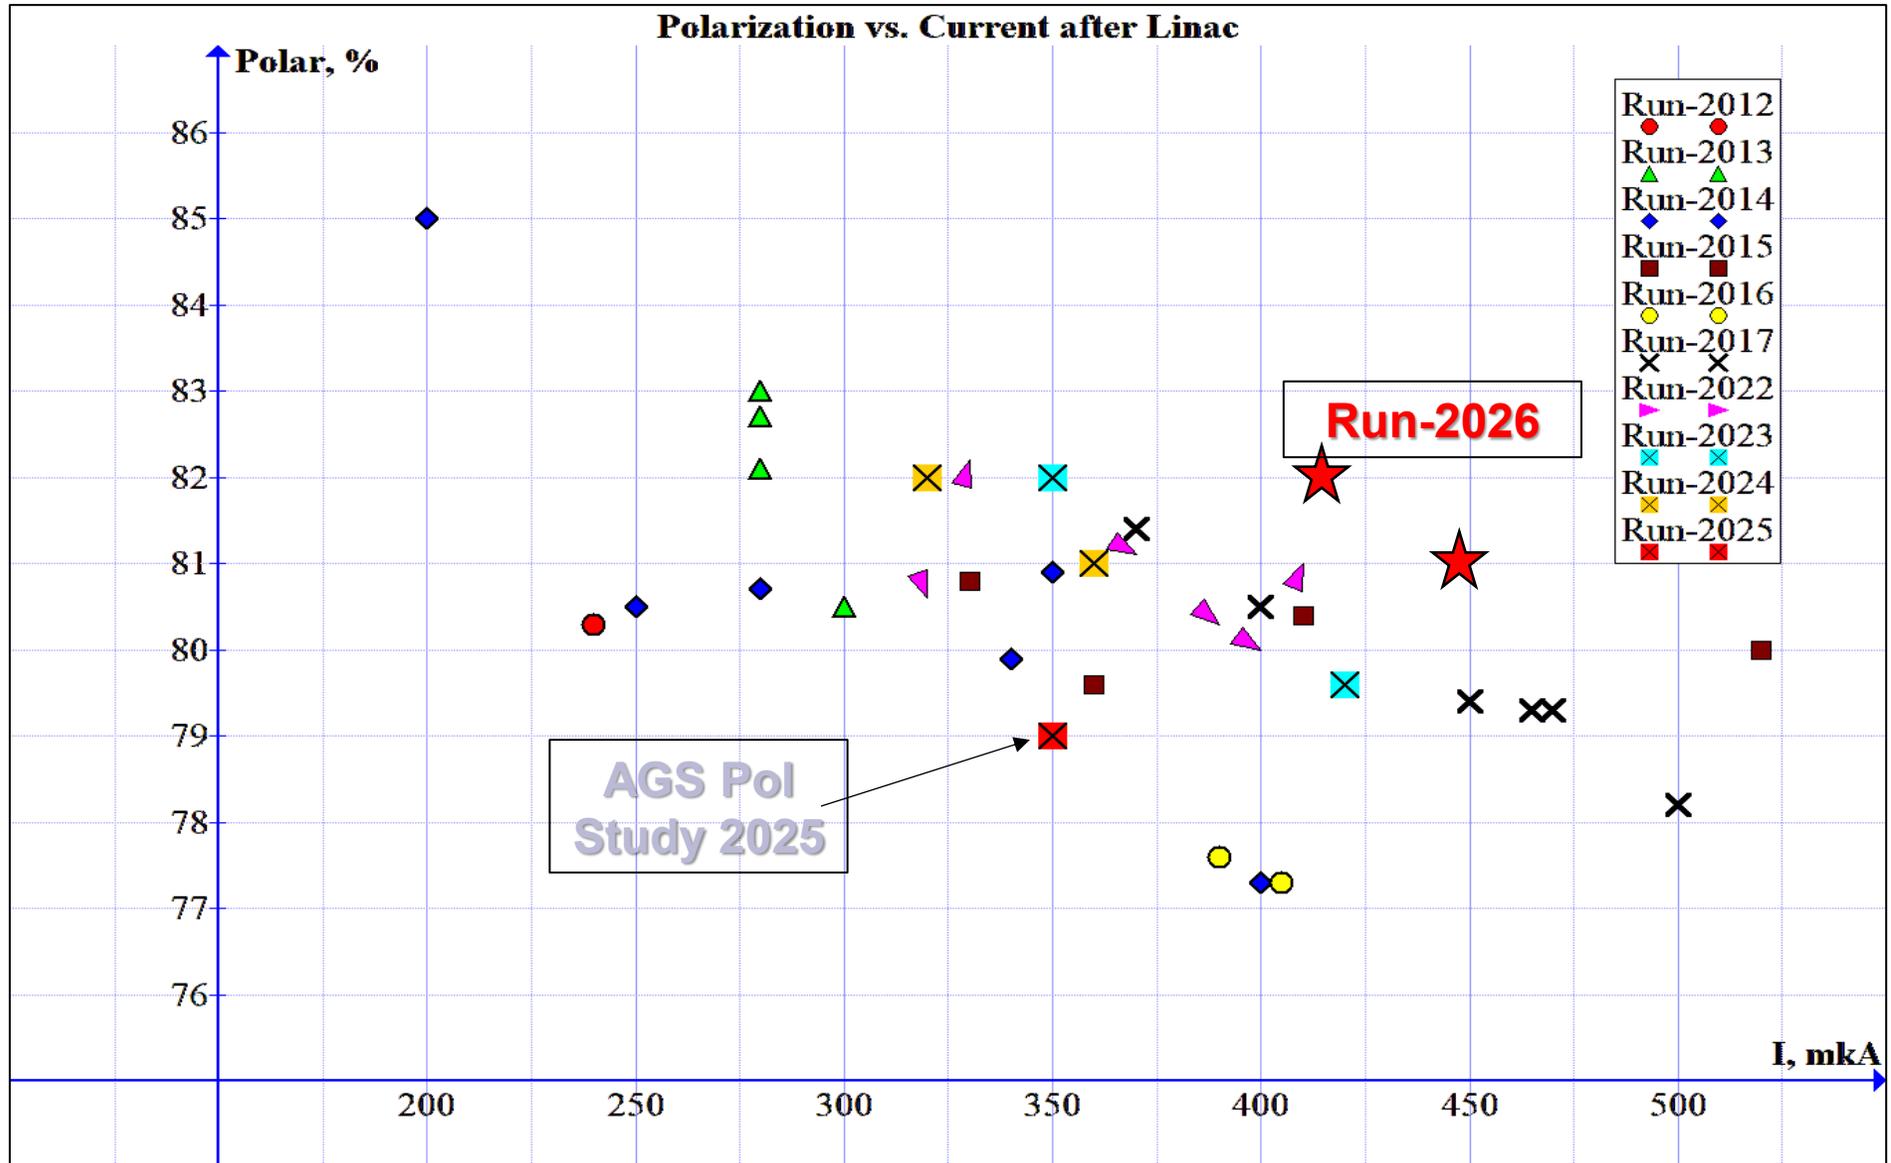

$\Delta I/I < 10^{-3}$ and $\Delta P/P < 1\%$ were measured in the RHIC OPPIS at Run-24.

Performance of source at RHIC RUN (Dec 9, 2025 - Feb 6, 2026)

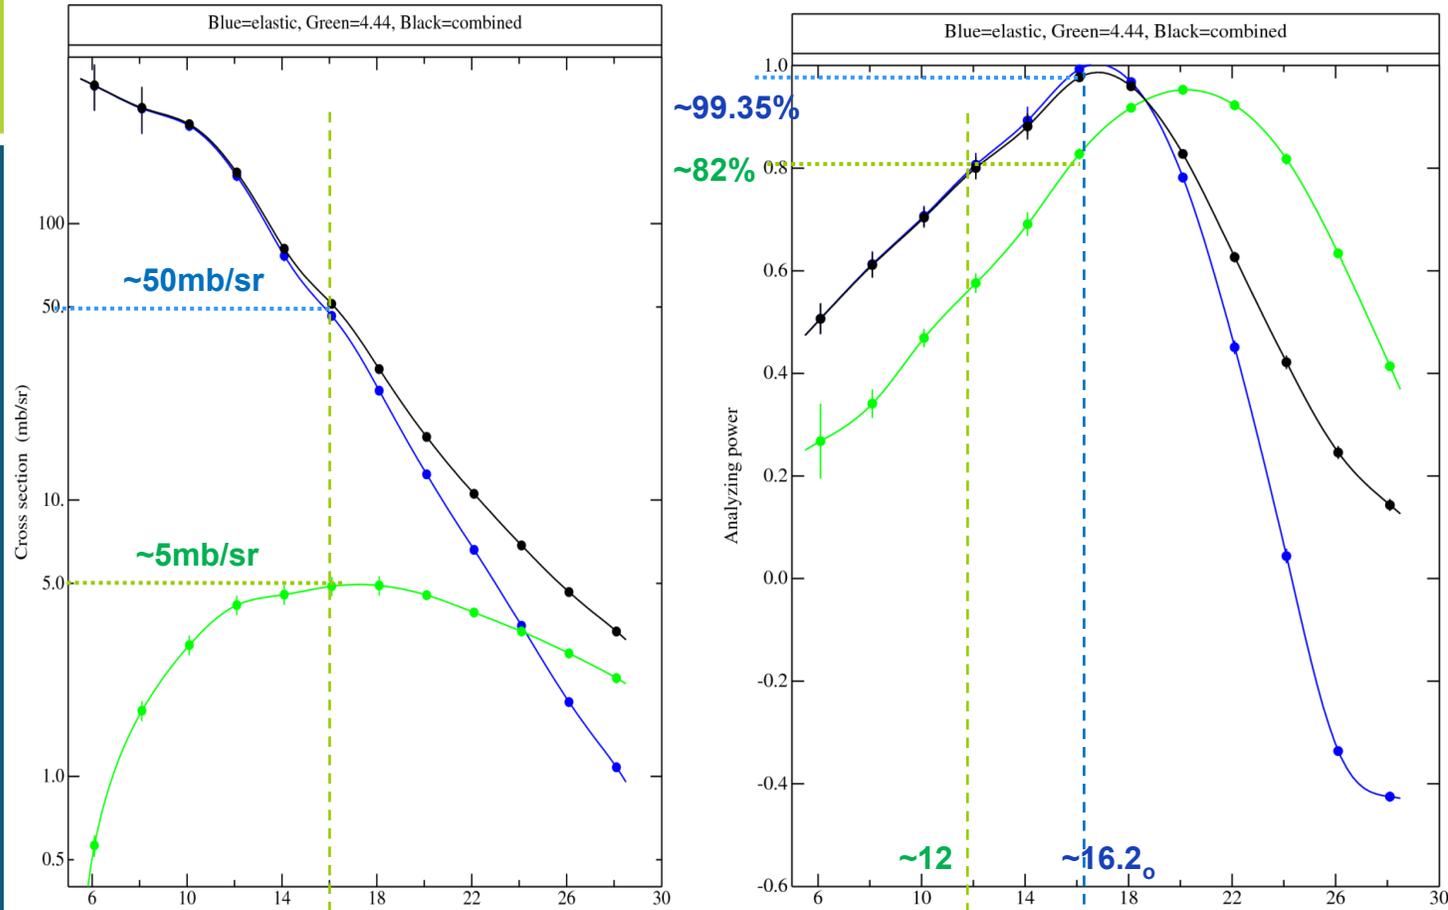

Beam performance at 2012-2026

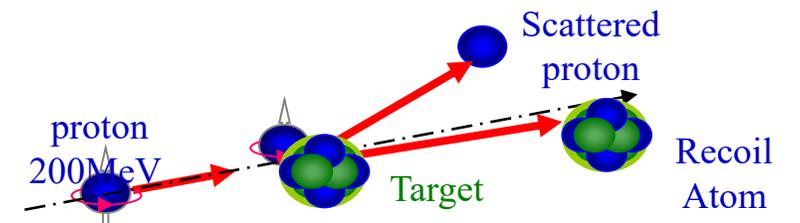

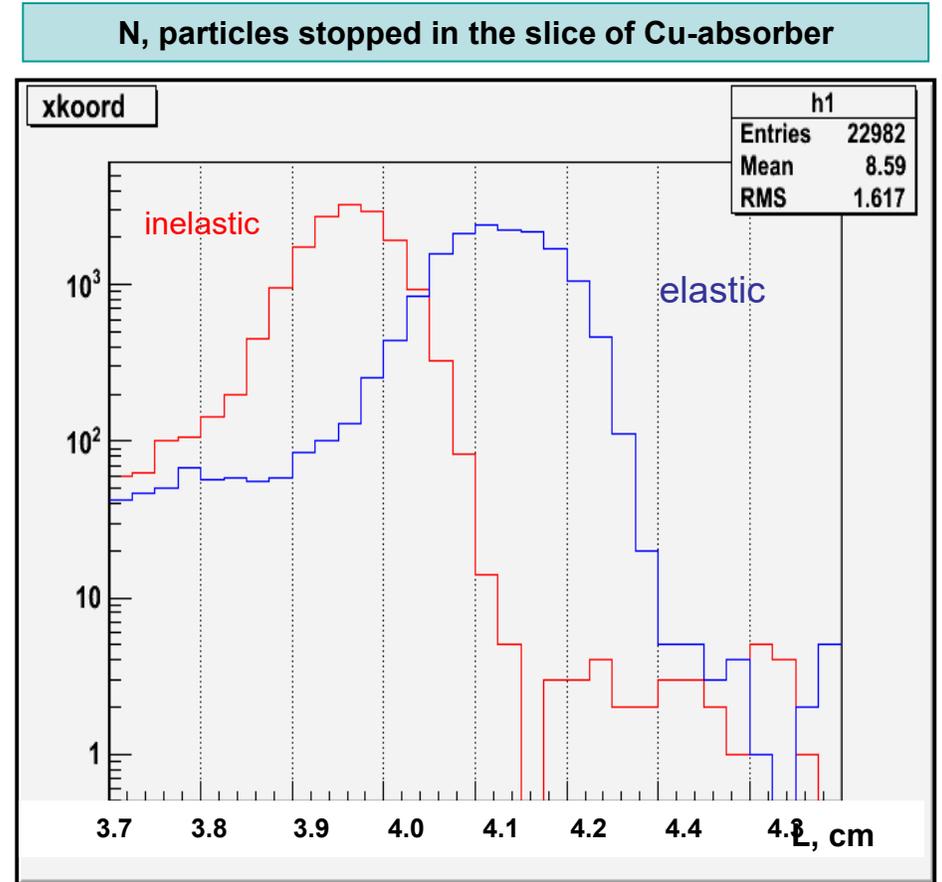

Precision, Absolute Proton Beam Polarimeter at 200MeV

Cross section and analyzing power for elastic pC scattering at 200 MeV

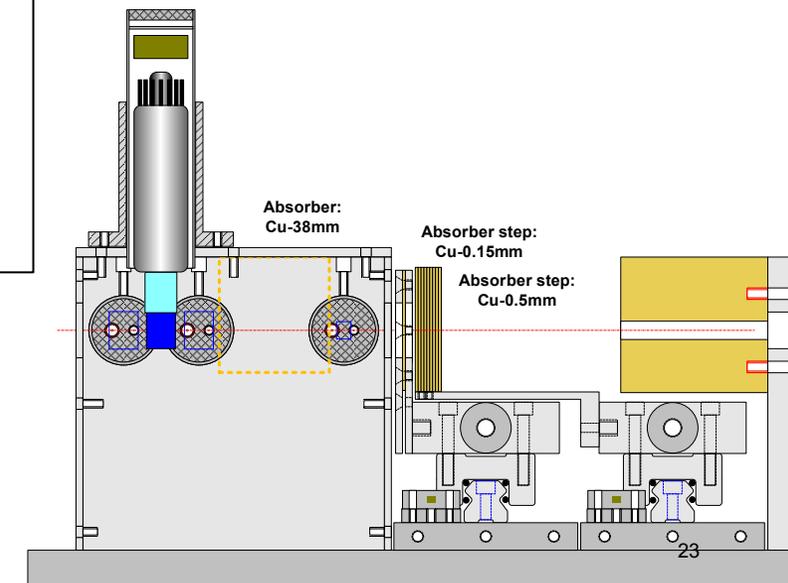

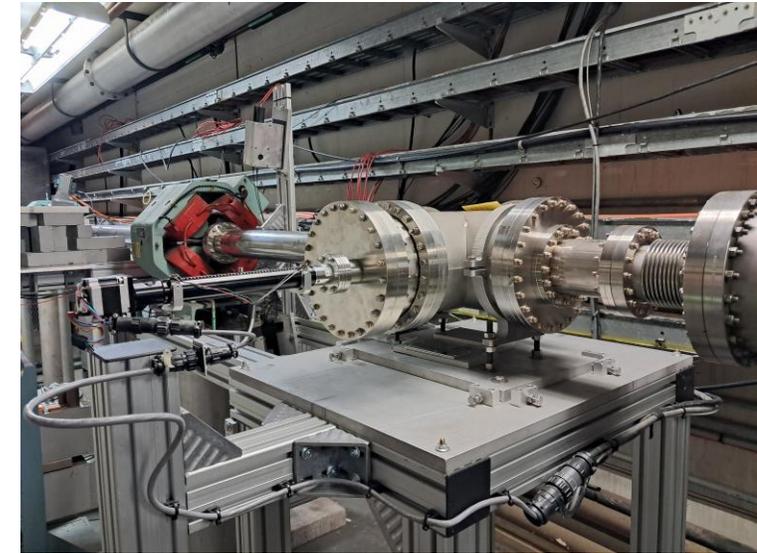

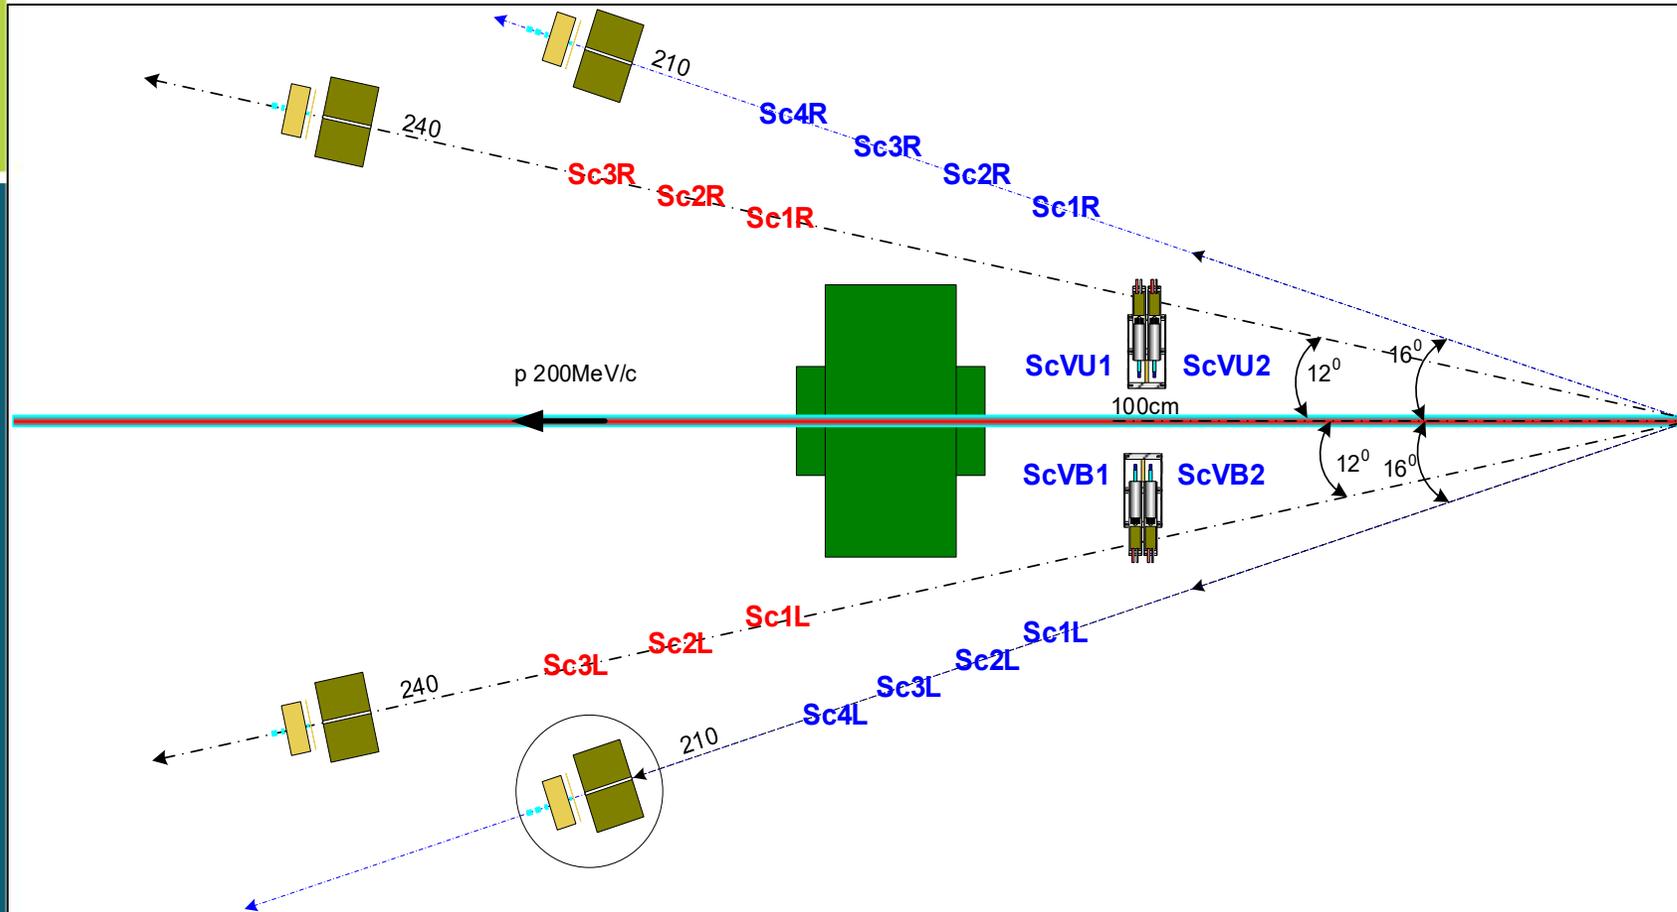

Measurements of the cross section and analyzing power for proton scattering from ^{12}C at 200 MeV. The blue curves correspond to the ground state protons of carbon. The green curve corresponds to the protons from the first excited state (-4.44MeV). The black curve represents the sum of the two data sets.

Ion Source Development

Since 2012, when FABS was implemented, we have made many adjustments to improve the beam parameters. We achieved the best polarization volume of over 85%, intensity over $1000\mu\text{A}$, and a beam pulse duration of over $400\mu\text{s}$ compared to the average volume of polarization at last run-26 of $\sim 82\%$ and an intensity of $\sim 420\mu\text{A}$.

Now, our goal is to have OPPIS maintain the best parameters for several months by improving monitoring and simplifying control, as well as making it fast and easy to repair and completely safe. Our goal for the future is stability and safety with the best performance.

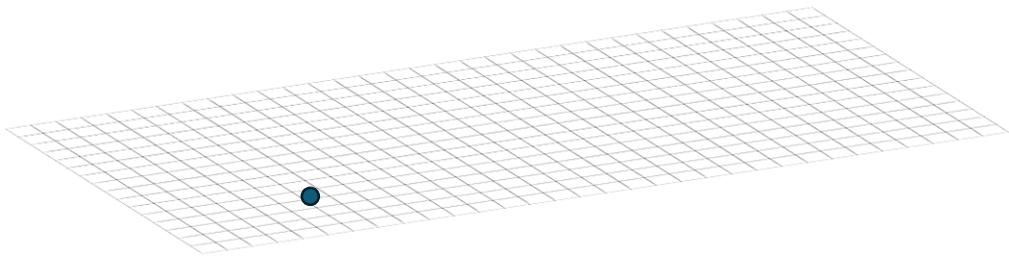

As a first approximation, the main parameters of the quality of the formed beam is intensity, polarization and emittance.

FABS Subsystems

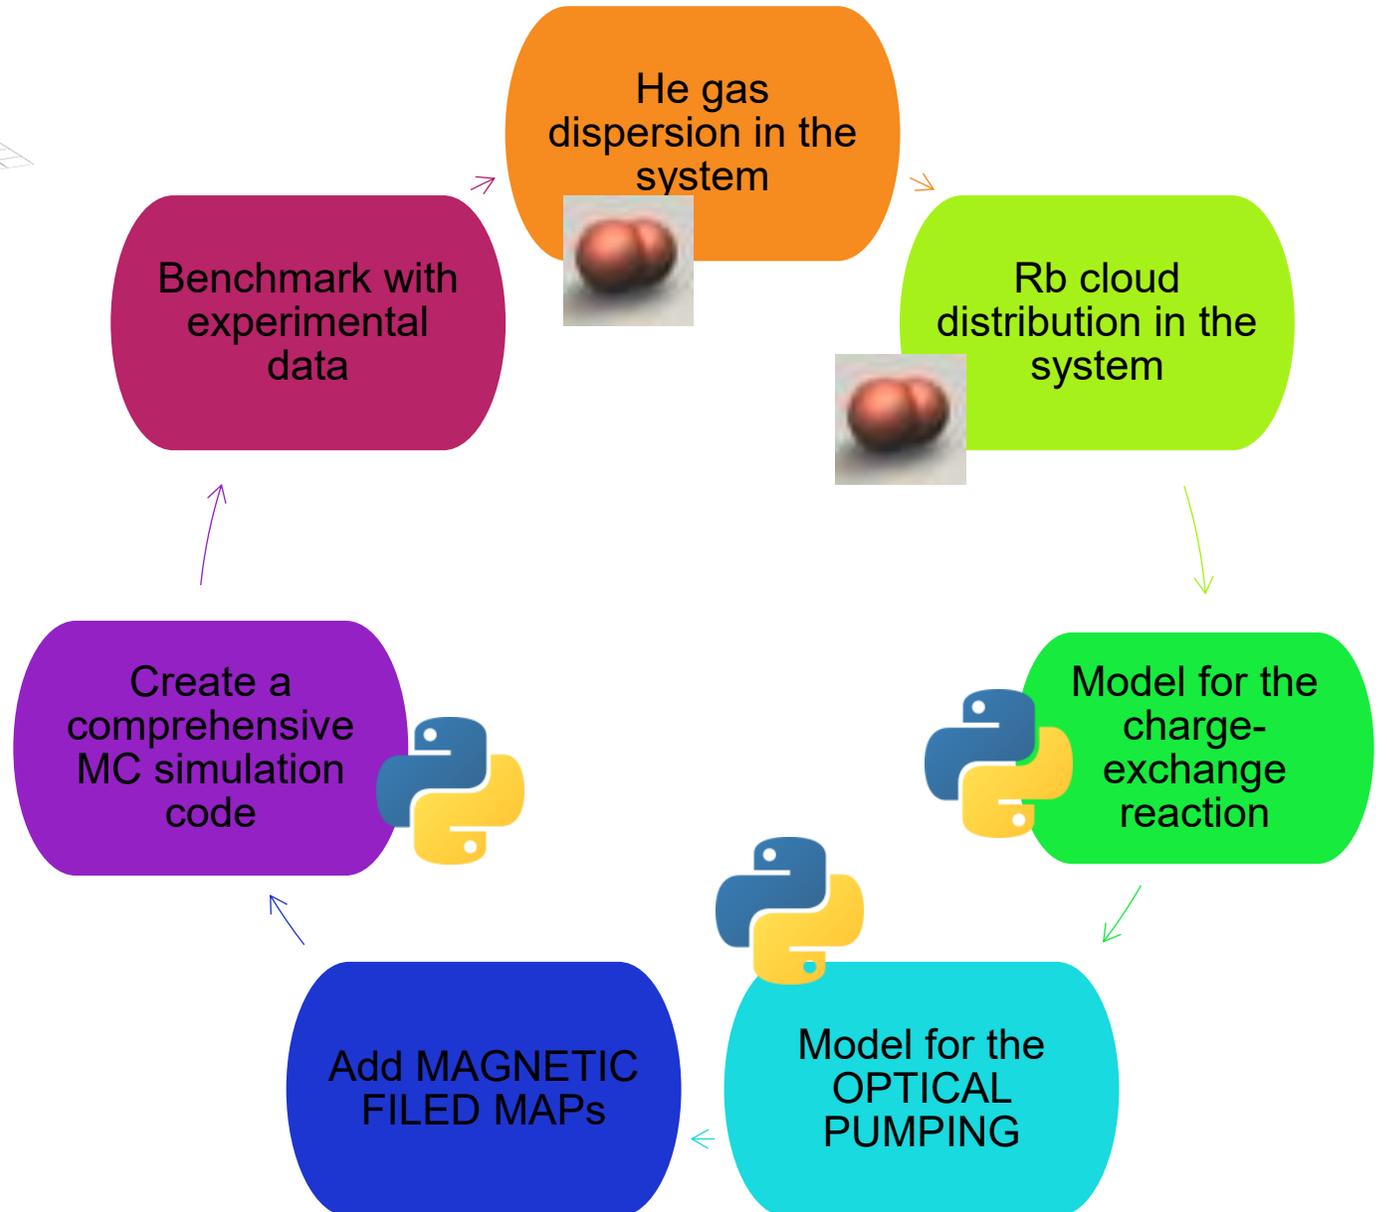

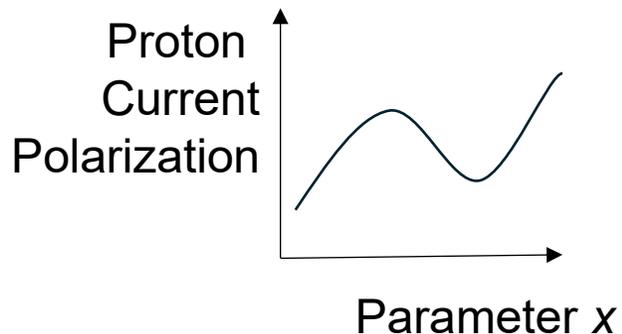

Subsystem	Critical components	Operational Status	MC simulation	R&D required	Rebilde	Power Suply
Plasmatron	Pulsed valve	Good		Yes	Yes	Yes

Summery

Significant work will be required to upgrade the source.

- Many components of this source are unique and commercially unavailable. They have undergone intensive operation over many years and require replacement.
- The obsolete components of source will be replaced with modern and more reliable systems.
- Based on the results of tests and measurements of individual source components, a comprehensive modeling system will be developed. This modeling will enable:
 - ✓ Optimization of the dimensions, geometry, and relative positioning of the elements (He-cell, Rb-cell, collimator system...);
 - ✓ Determine the optimal distribution of He gas, Rb vapor, Na jet, etc.;
 - ✓ Determine the magnetic field configurations of the SCS, LCC, Sona-solenoids and Na-solenoid, with the aim of maximizing polarization;

...

The combination of hardware upgrades and advanced modeling will enable the optimization of the OPPIS source to achieve higher beam current and polarization values, as well as the development of a polarized proton source for the EIC with the required parameters.

Backup

Plasmatron (cathode and pulse-valve)

One of the most important elements of plasma formation for a stable operation of the source is the **pulse valve** for injection of the hydrogen-containing gas and the **cathode** (arc current $\sim 500A$).

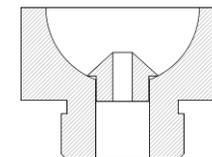

Pulse valve

The pulse valve has been upgraded several times to provide precise control and long-term stable hydrogen supply to the plasmatron to form a stable plasma.

The same type of valve is used in the helium neutralization cell.

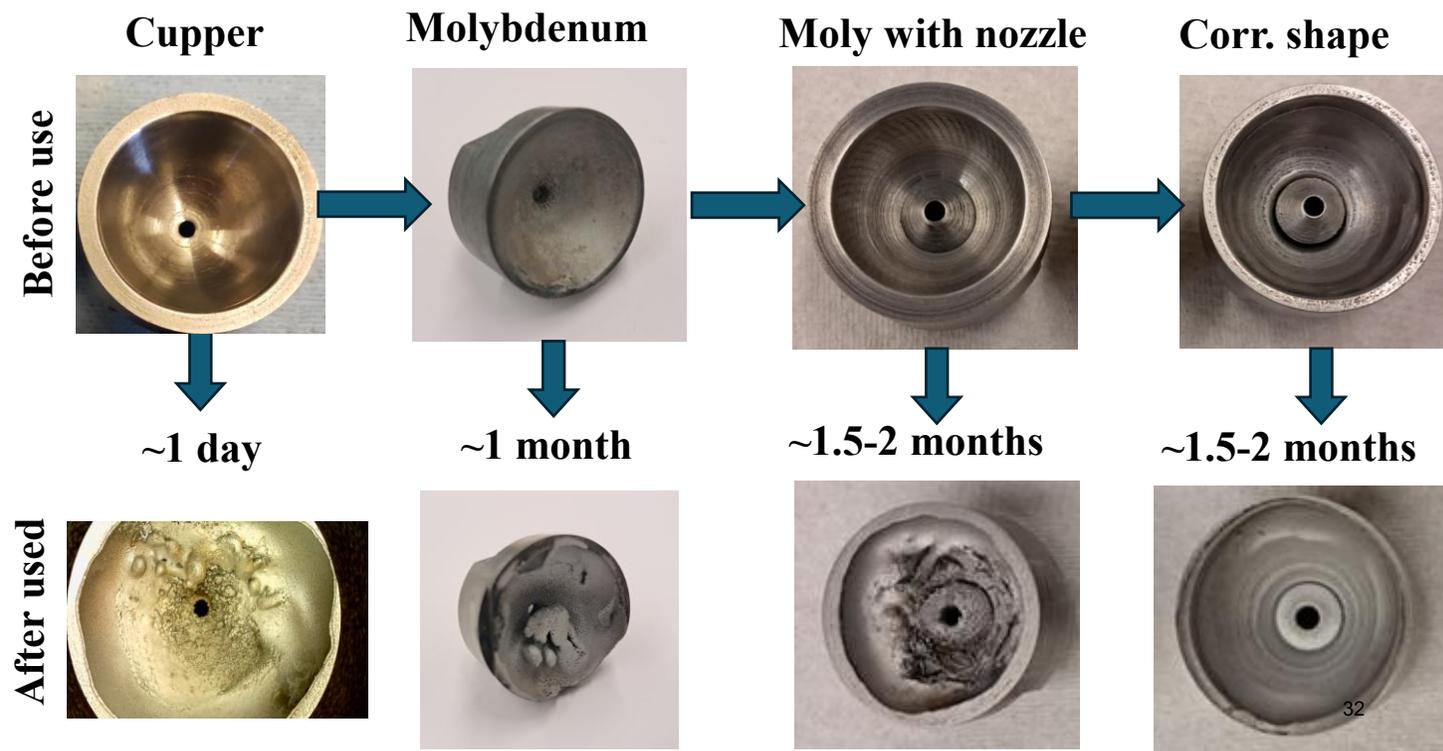

Cathode

The original copper cathode ($\sim 1085^{\circ}C$) in this high current cold cathode only lasted a few days ($\sim 5 \cdot 10^5$ arc pulses). Using molybdenum cathode ($\sim 2600^{\circ}C$) significantly improved the service life to $\sim 5 \cdot 10^6$ arc pulses ($\sim 1-2$ months).

Improving the geometric shape of the cathode by inserting a small nozzle and enlarging the outer rim, as well as improving the vacuum sealing of the plasmatron, limited the plasma dispersion, and increased the service life by more than 10^7 arc pulses (RUN-24).

FABS 4-grid (spherical) Ion Optical System with “geometrical focusing”

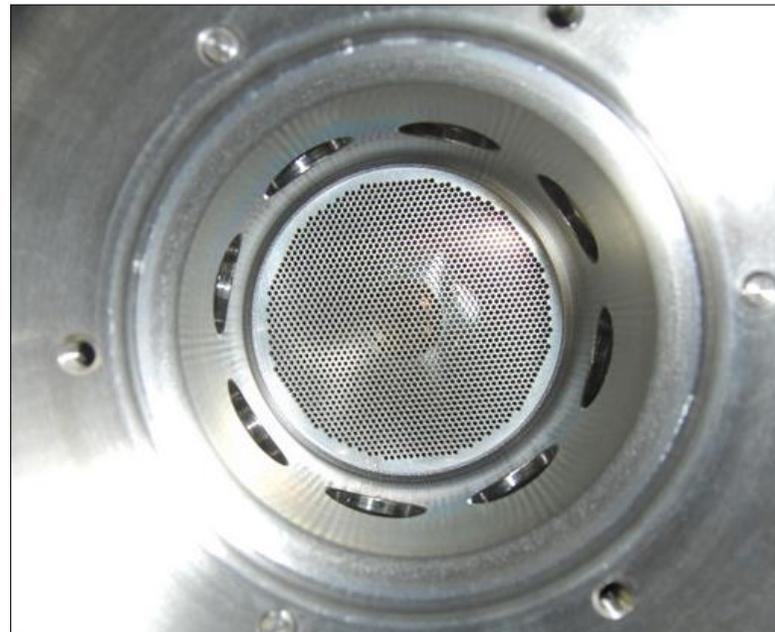

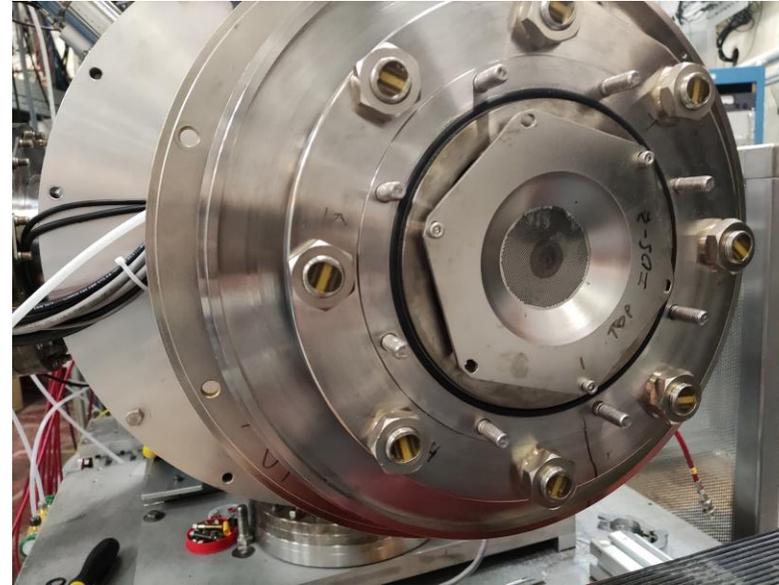

Grids system made by 0.4 mm thick molybdenum plates.

N grids = 4
 Diameter of grids ~ 50 mm
 N holes = 1820
 Diameter of holes = 0.8 mm
 Step of holes = 1.1 mm
 Transparency ~ 53 %

Radii of the spherical grids:
 R1~ grid1 ~ 180 cm
 R2~ grid2 ~ 150 cm
 R3~ grid3 ~ 120 cm
 R4~ grid4 ~ 120 cm

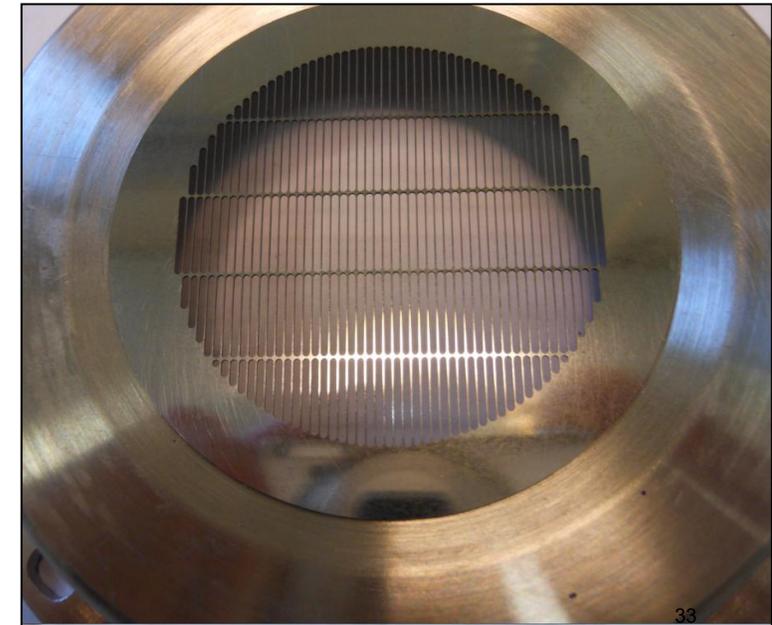

Gap of grids:
 1→2 ~ 0.4-0.5 mm
 2→3 ~ 1.0-1.4 mm
 3→4 ~ 0.4-0.5 mm

Proton energy ~ 5-10 keV
 Intensity ~ 2.5-5.0 A

IOS#	I^0, A	F, m	a, mrad	H^0, mA	H-, mA
1	3.5	170	12	270	9
2	3.2	300	7	730	22
3	3	280	8	650	20

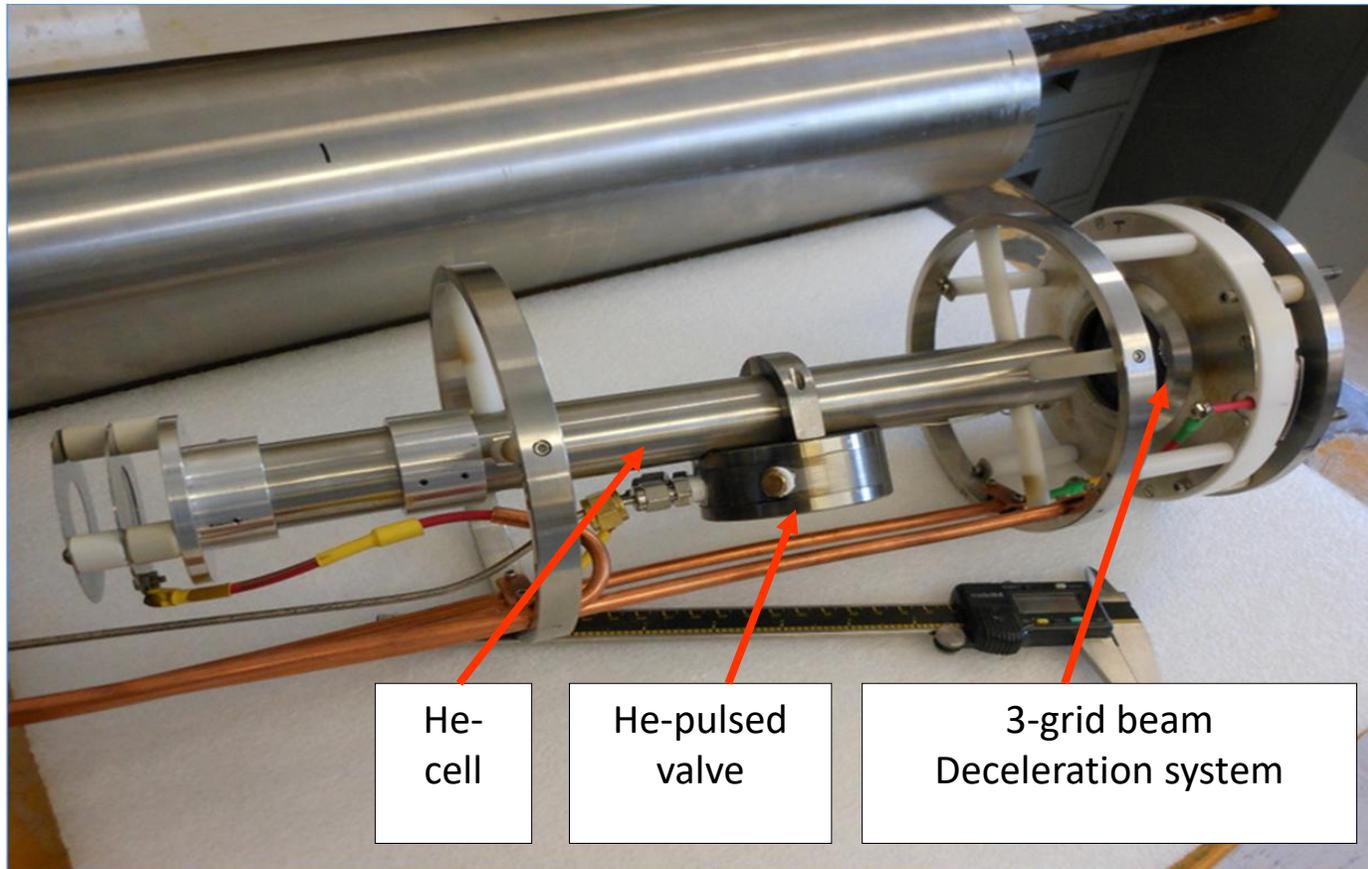

New slit-type IOS grid for higher brightness beam formation

He-ionizer cell and 3-grid deceleration system

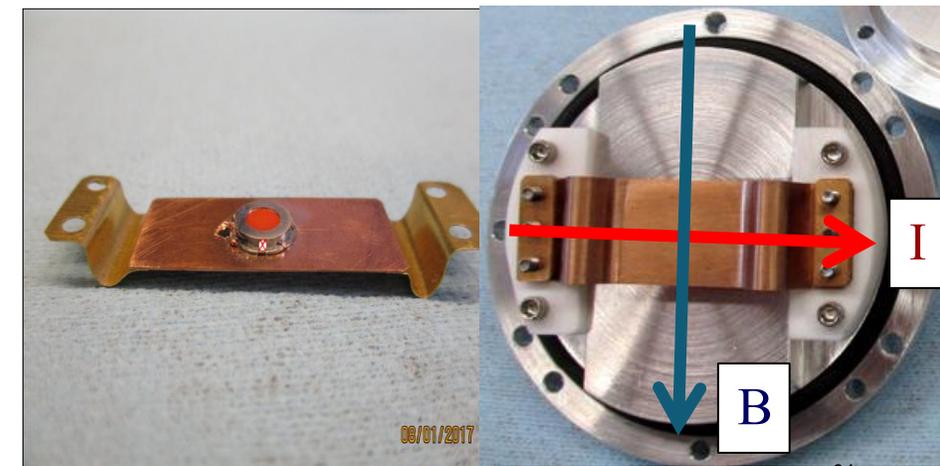

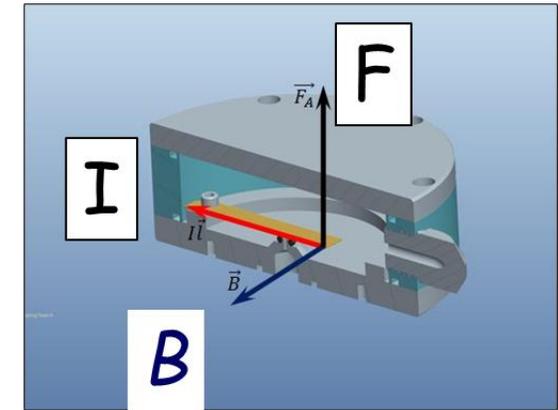

Two functions of the new He-cell with pulsed valve:

- Ionization of the injected neutral beam in the He-cell
- Deceleration of the ionized part of the beam by 3-grids system to separate from the not ionized part

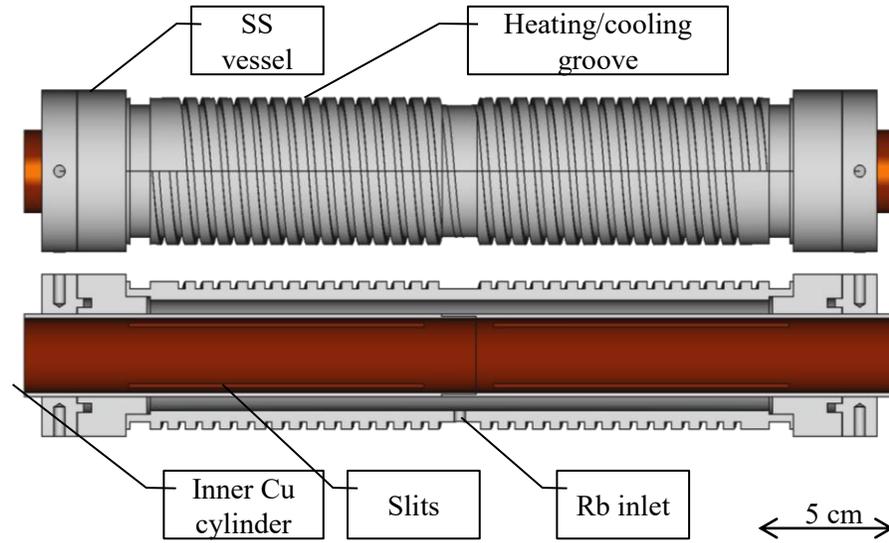

“Electro-magnetic” pulse valve

Lorentz (Laplace) force moves the flexible conducting plate in the high ($\sim 2-5$ T) magnetic field. For $I=10$ A, $L=5$ cm, $F=2.5$ N. Current pulse duration $\sim 100-300$ μ s

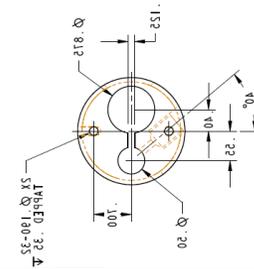

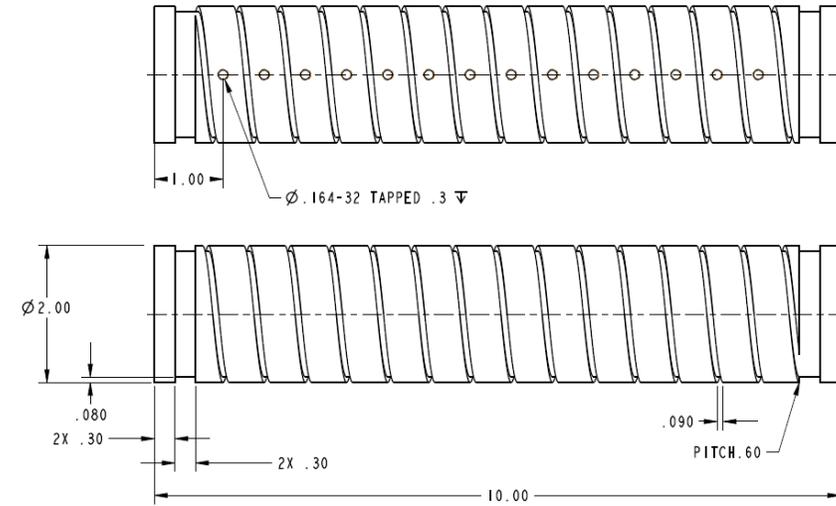

Neutralizing Rb-cell

SS Cell (Run24)

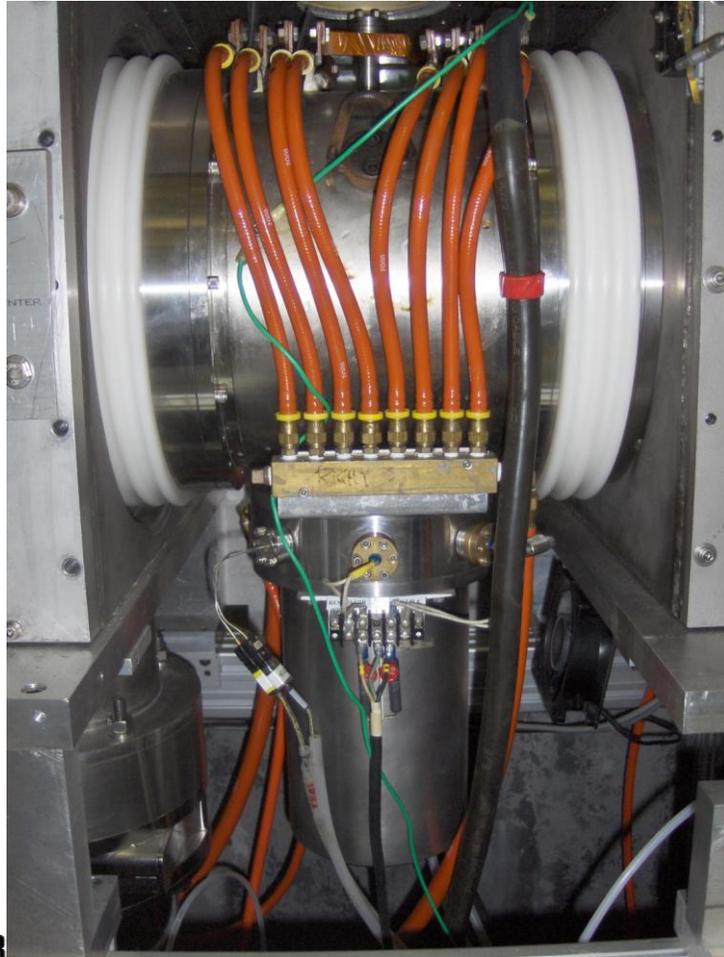

Copper Rb-cell

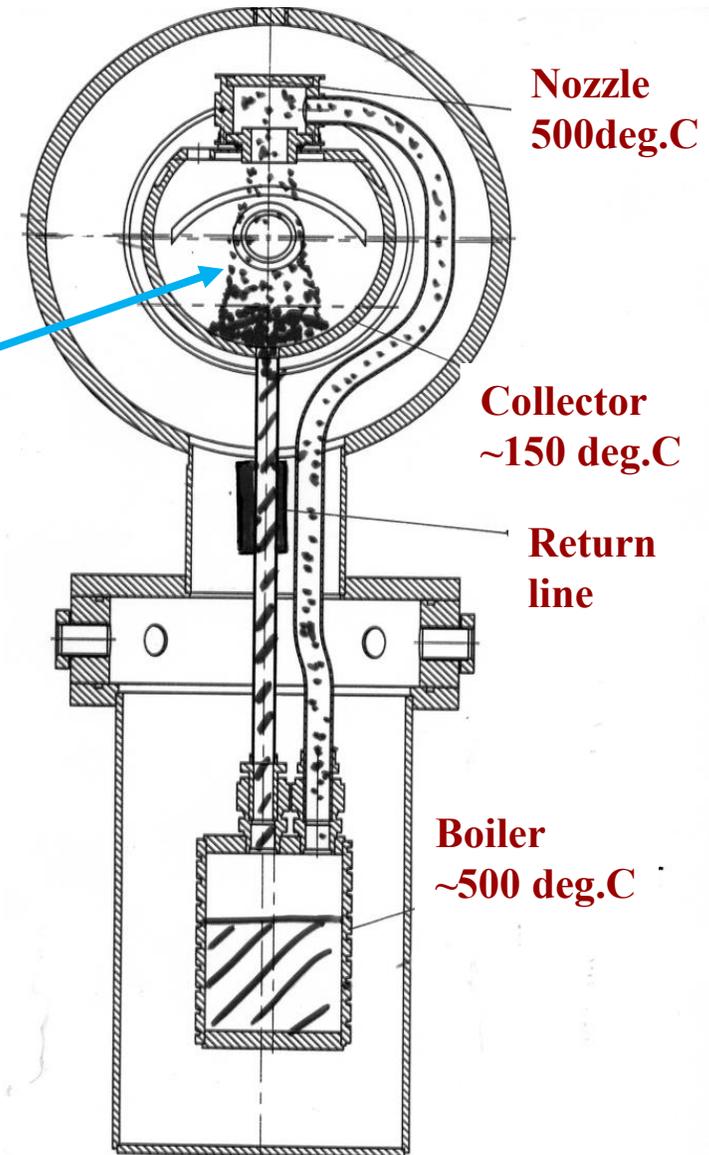

Sodium-jet ionizer cell

Transversal vapor flow in the Na-jet cell. Reduces sodium vapor losses for 3-4 orders of magnitude, which allow the cell aperture increase up to 3.0 cm .

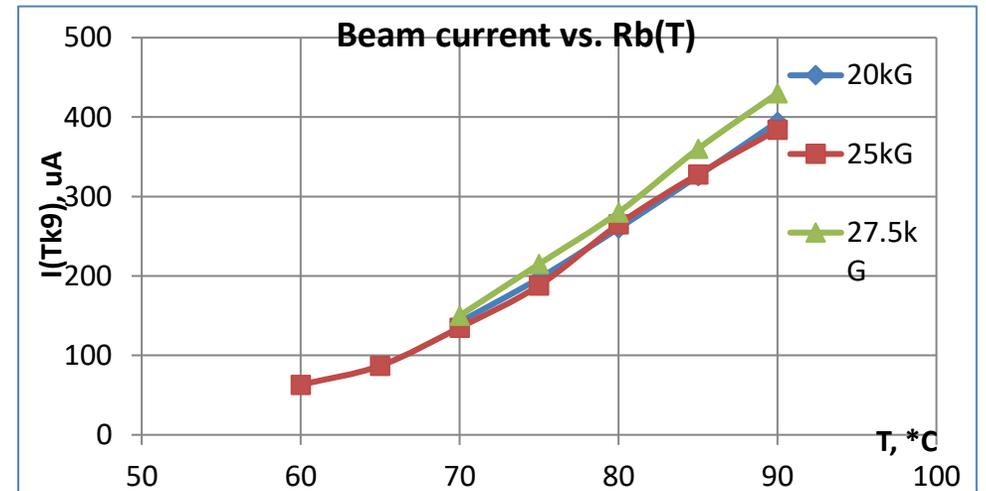

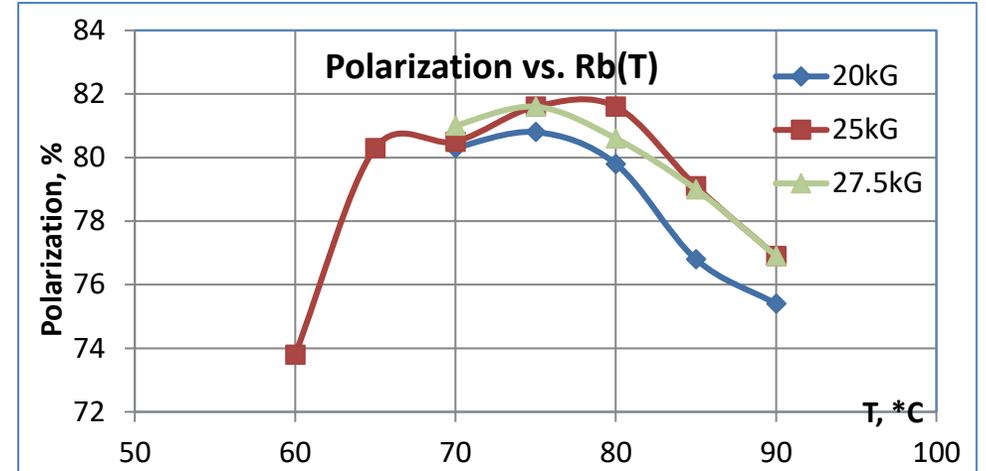

NL $\sim 2 \cdot 10^{15}$ at/cm²
L $\sim 2-3$ cm

Superconducting Solenoid

The Solenoid is fully re-condensing with no measurable helium losses. 152 mm in diam. warm aperture, total length-115 cm. Flattop magnetic field ($\pm 0.5\%$) is ~ 65 cm.

Depolarization factors

Depol. factor		Process	Estimate
1	E_H^0	Dilution due H^0 part of the beam (LEBT)	0.99 - 0.99
2	P_{Rb}	Rb-optical pumping (Laser system)	0.99 - 0.99
3	S	Rb polarization spatial distribution (Collimators)	0.97 - 0.98
4	B_{RG}	Proton neutralization in residual gas (Vacuum)	0.98 - 0.99
5	E_{LS}	Depolarization due to spin-orbital interaction	0.98 - 0.98
6	E_{ES}	Dilution due to incomplete energy separation not polarized component of the beam (LEBT)	0.98 - 0.99
7	E_{Sona}	Sona-transition efficiency (Adjustment)	0.96 - 0.98
8	E_{ion}	Incomplete hyperfine interaction breaking in the ionizer magnetic field	0.98 - 0.99

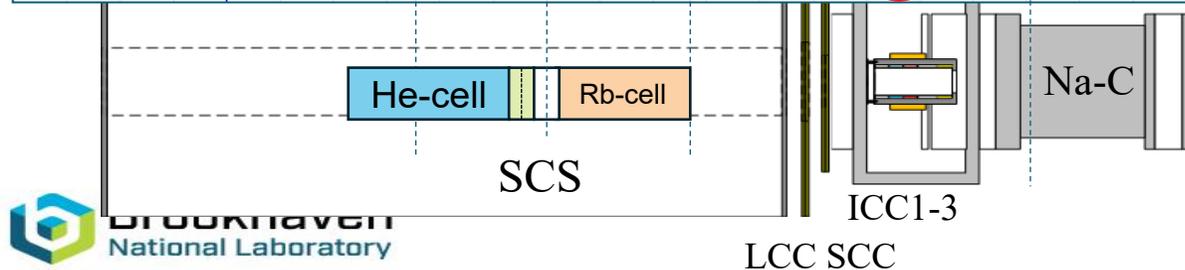

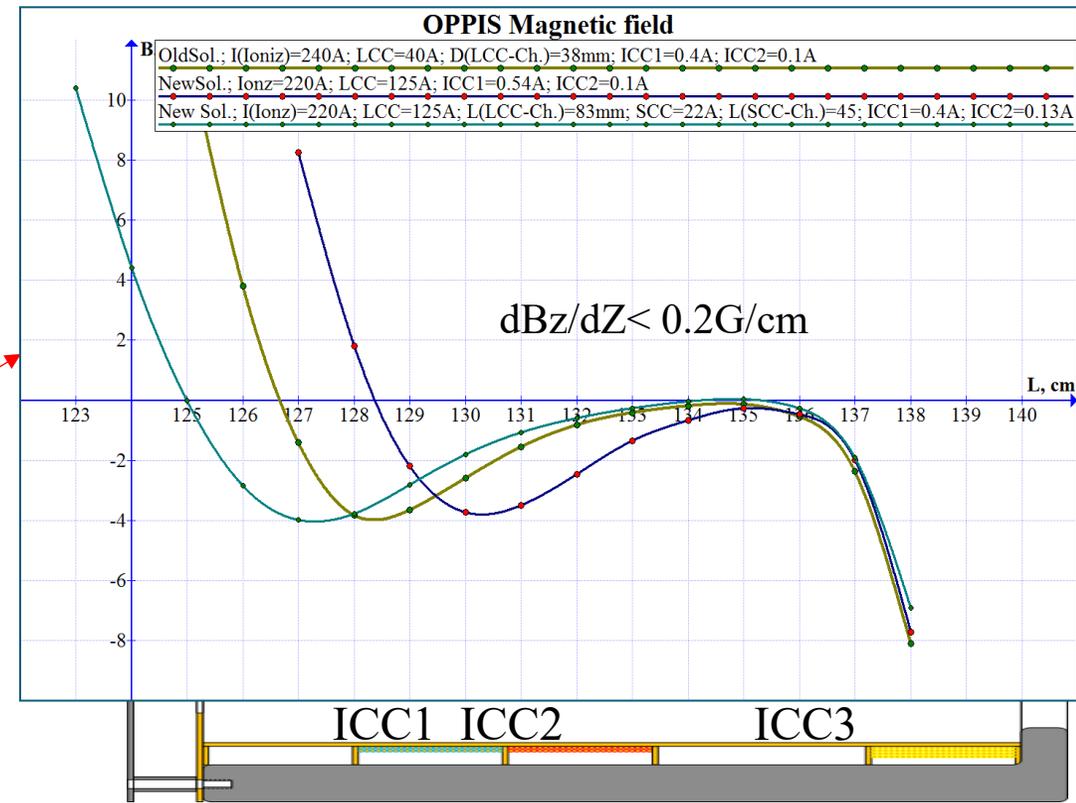

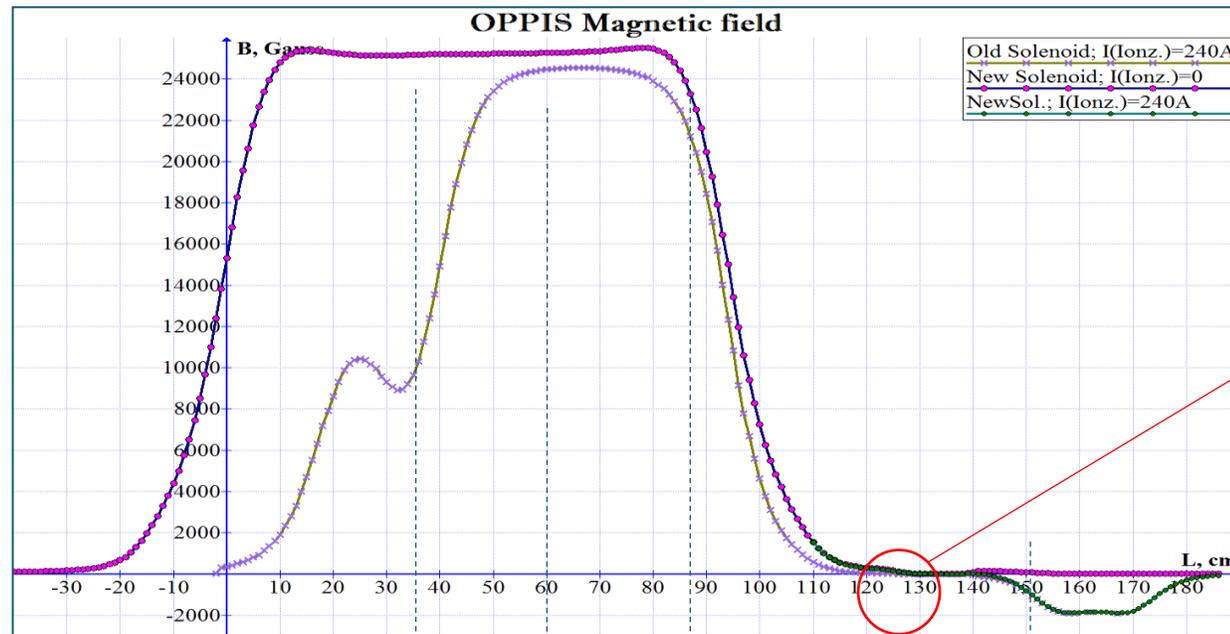

Total: 0.85 - 0.90

$$P = E_H^0 \cdot P_{Rb} \cdot S \cdot B_{RG} \cdot E_{LS} \cdot E_{ES} \cdot E_{Sona} \cdot E_{ion} \sim 85-90\%$$

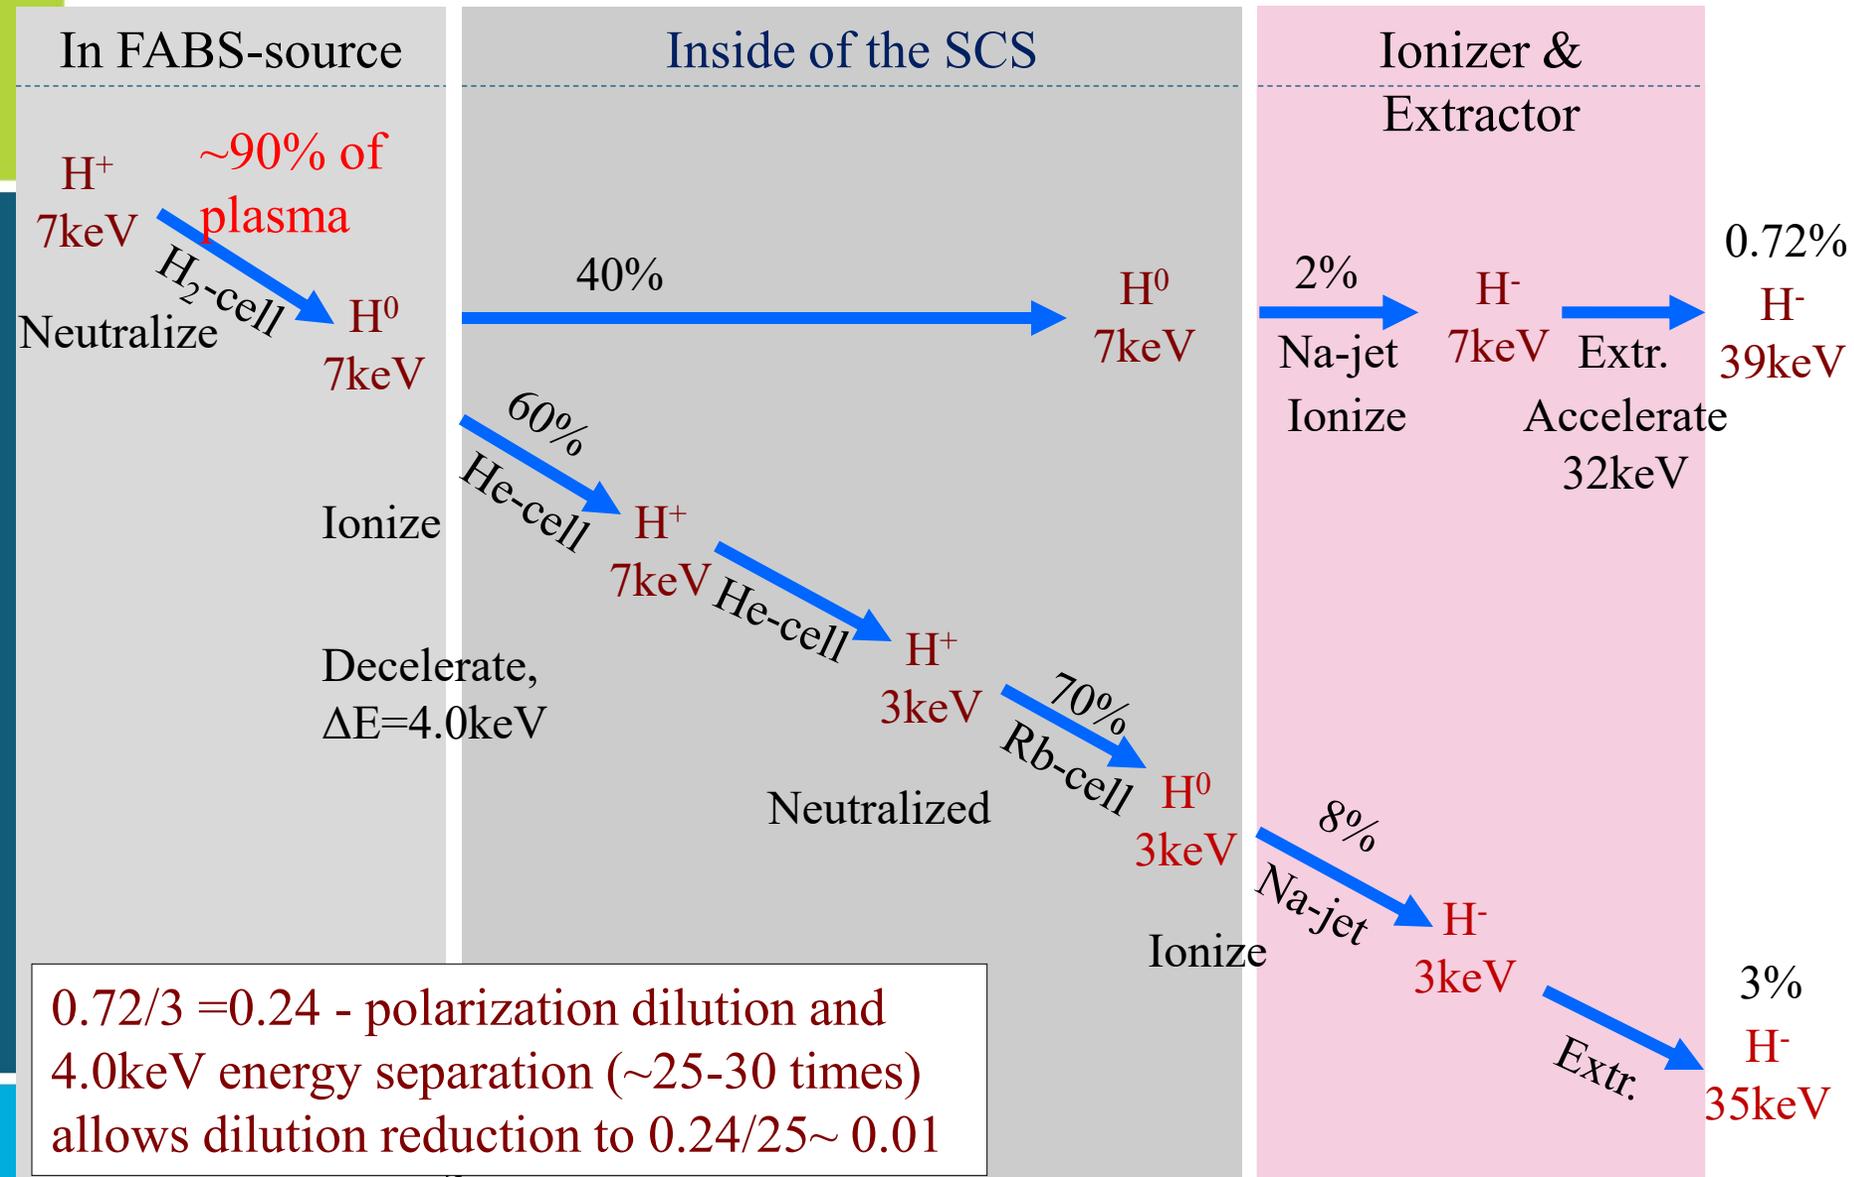

Sona-transition efficiency

The shape of the magnetic field in the "Sona Transition" area depends on the following factors and can be adjusted by:

- The optimization of the solenoid position;
- 2 correction coils (LCC and SCC) with the field in the opposite direction to the SCS;
- 3 correction coils (ICC1-3) for fine field tuning inside the “Sona Transition”;
- “Sona-shield” (soft steel cylinder- of 100 mm diameter and 120 mm length).
- Na-cell coil (Na-C) - solenoid around sodium ionizer.

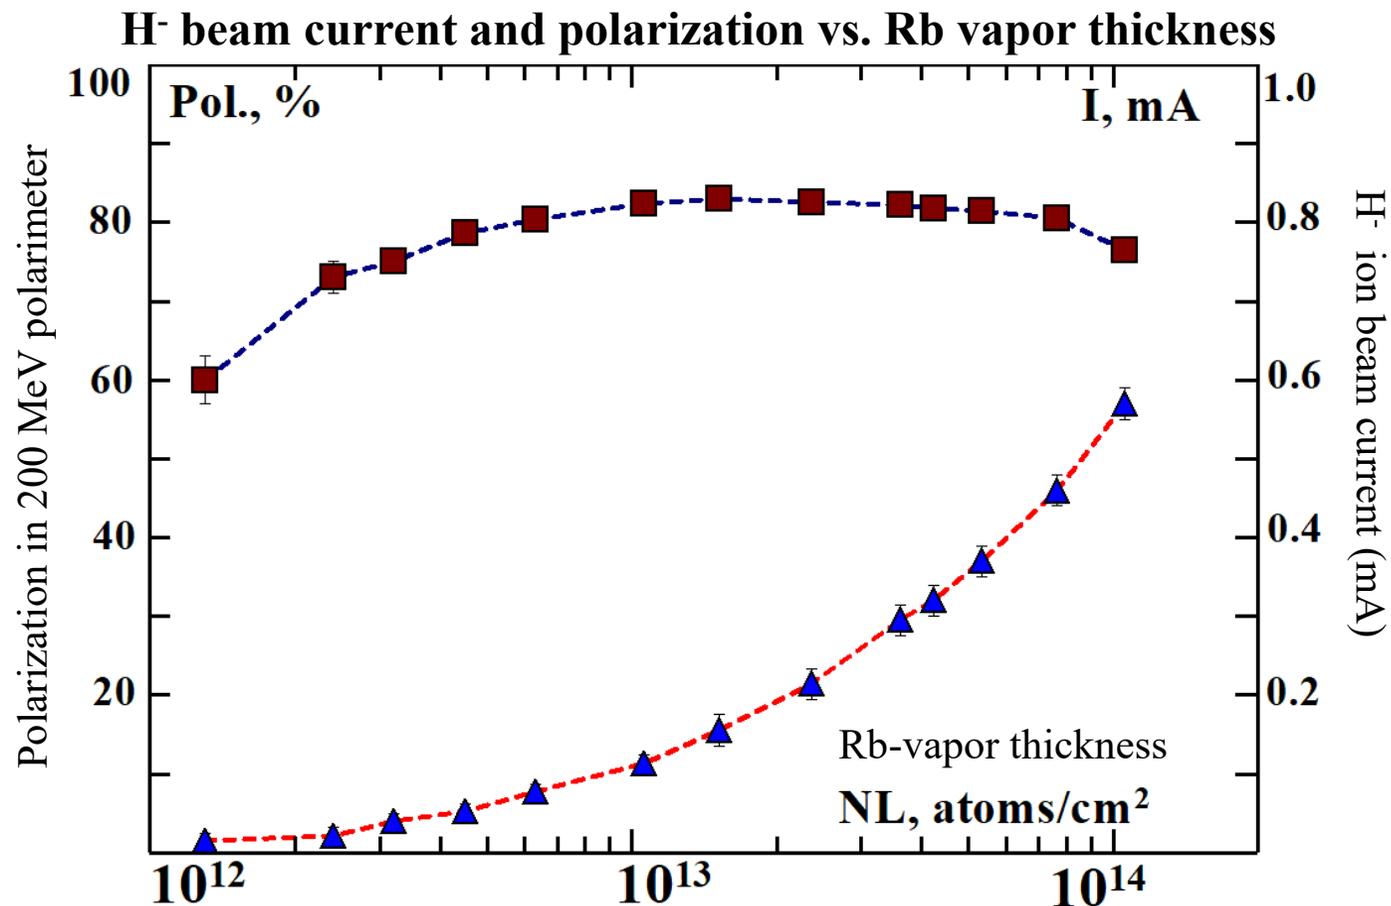

Polarization dilution due H⁺ in the new source

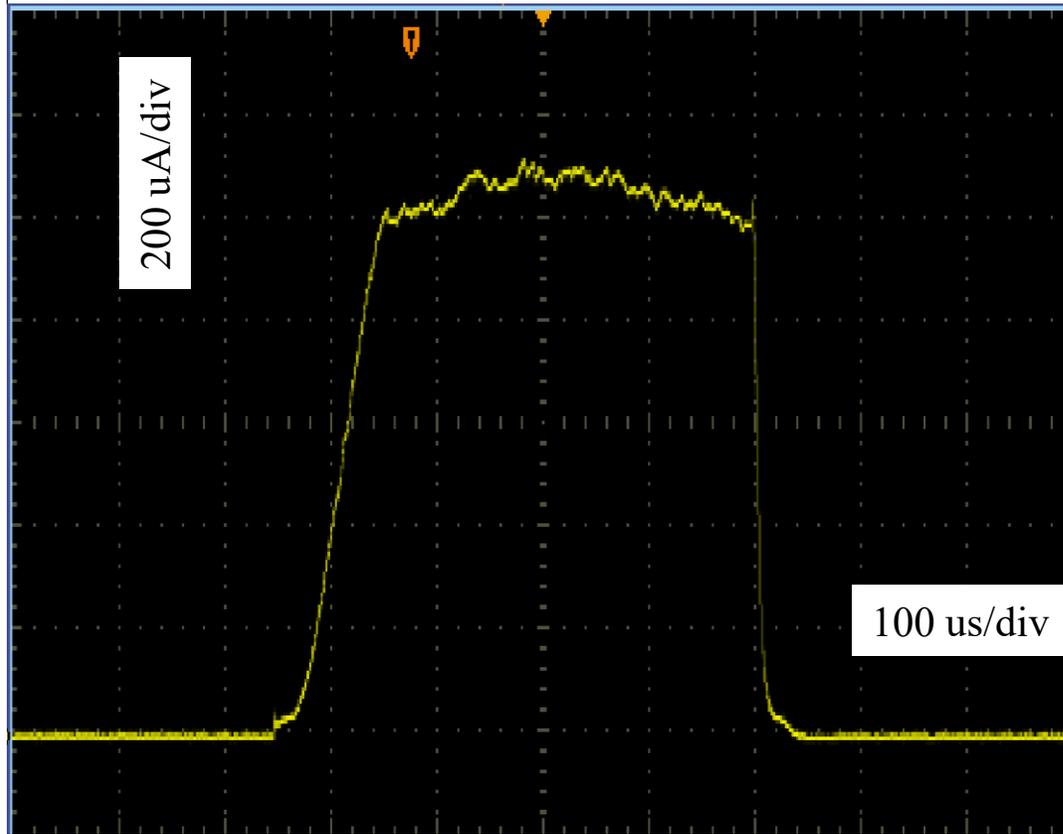

0.72/3 = 0.24 - polarization dilution and 4.0keV energy separation ($\sim 25-30$ times) allows dilution reduction to $0.24/25 \sim 0.01$

H⁻ beam current and polarization at 200 MeV

200 MeV polarized proton after Linac

Polarized H⁻ current-1.05 mA, after RFQ 750 keV

$\sim 620 \mu\text{A} \times 400 \mu\text{s} \sim 1.5 \cdot 10^{12}$ p/pulse after LINAC
